Be careful not to confuse the above definition with those for primary and secondary data. When we talk of primary sources we are obviously referring to something that is published and exists whereas with primary data it will not exist until a researcher defined, locates and collects it.

5.5 Basic Writing Rules

For Study projects a full literature review will be needed but in Engineering projects the requirements document forms part of the Literature Review. However, even in Engineering it is necessary to write a short review just to form a technical backdrop to your project. It may help you to remember there are two cardinal rules when writing – they are simple:

Respect – always have a deep respect for ones readers and make it easy for them to understand what you are saying.

Need - only quote, paraphrase or summarize when it clearly adds to what one is saying. The key task is to formulate ones own ideas, in your own words but one does this by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

5.6 Literature Assessment

When assessing this element the University will look at how YOU use the sources in what you write and at the range of sources that you use. If either is judged deficient your work may not be accepted as the view taken will be that you are not prepared for work at this level and on this topic. It is expected that all your sources will be mostly primary ones. If there is some reason why this is not possible it must be discussed with the Research Methods tutor or your project supervisor.

5.6.1 Literature Review Ideas

All the following steps are iterative and you must expect to go backwards and forwards many times before you get a review with which you are happy.

Reading/Writing with the Intellect - This is normally thought of as a four stage process that applies equally to what is written (because it is going to be read by someone).

Understanding – this is simply taken to mean that we understand the words used.

Interpretation – are able to find meaning in the words used.

Evaluation – we ask does the meaning have any value – in essence we ask is it true or false.

Contextualization – this implies that everything we read is coloured by what we already know. This idea is taken much further in the idea of hermeneutics (see the notes).

Usage – the literature that you find and evaluate can be used to supplement your own work and demonstrate your mastery of the topic area. This does not mean that you quote, paraphrase or summarise everything you see. As a rule of-thumb: only quote, paraphrase or summarise when it is necessary and it is not common knowledge and it is not an obvious observation.

Argument - Finally, keep in mind that when writing you are dealing with a form or argument where you are trying to persuade your reader about some point or other and that should only be attempted when you are knowledgeable, the argument is essential and you have a deep respect for your readers.

5.6.2 Literature Review Construction

Here is a plan that you can use to construct your own review. It is not infallible and will require conscious effort from you and it must be based on a thorough evaluation of the literature.

Step 1. Purpose - the purpose is to fully prepare your mind with all that you need to know about the topic area and the particular element of it that you are focusing on. The idea is that what you write shows your mastery of the topic and in fact you have become an authority on the topic area. So a review is not a long list of quotes, paraphrases and summaries, it is an evaluatory discourse. That is, readers will want to know what YOU have to say based around what you have uncovered in the literature - so readers must see what you have found and see what you have to say about it.

Step 2. Topic and Aspect - Make sure you are clear about your topic area and which particular aspect of it you need to explore and understand in order to be able to effectively carry out your planned research.

Step 3. Select a Theme - Use your project problem definition, target and outcome to guide you in selecting a theme that will connect all the various elements of your review together making it a lucid and progressive discourse. (Don't be afraid to alter the theme as you go along if that becomes necessary)

Step 4. Your own Views - Try to make a list of your own views, ideas and knowledge. Remember, the review is an evaluation of what you find not a recitation of it. If all you do is tell us what you have found you may not even pass because almost anyone can write a review on any subject if all that is required is to more or less recite what has been found. So you must structure the review around your theme and your own ideas and thoughts.

Step 5. Make a Review Content list - Based around your theme make a list of all the various topic strands that you need to know about. It may help you to think about strands such as: organisational, administrative, functional, social, technological, cultural, ethical and so on or some other structure best suited to your topic – but it must be progressive and logically take you through the topic area. This is not about writing down everything you know it's about giving your readers a focused discourse on your chosen topic area. Commonly it is found that it is useful to start as follows.

5a. Basic definitions and terms that need to be clear for the core topic area. (Be careful to note any abbreviations)

5b. Map out several important areas or problem space dimensions. Now it is impossible to be general here so for example if I were looking at mobile devices and their use in business I might map out the following elements: value, attitude, use, limitations, practice cost, ease of use, learning curve, effectiveness and so on. Please be careful here to look for significant things not just drag in anything and everything. Once you have made this list you may add to it, modify it or discard from it as you go along.

5c. Work out how you want to end the review - often this just sums up your point of view but you may have other ideas

5d. You may like to include some statistics if that is relevant. But don't let this run away with you and so the review just becomes some sort of justification based on statistics. Remember, statistics almost never tell us anything about the topic itself and only tell us things related to the relative importance of certain things we have identified.

Step 6. Literature Searching - Armed with your theme and list of elements start your search for suitable material but be very careful to record the exact details of where everything may be found and checked. The search may start with the Internet or a special tool like Google Scholar but must move on to respected publications.

Step 7. Structure - The final step is to structure your themed list of topics using headings, subheading, paragraphs, bullets, tables, diagrams and so on in order that we get a coherent and lucid discourse on your chosen subject area. This is not a trivial matter and you must expect to go over it many, many times before it is really an example of your very best work.

5.6.3 Reference and Bibliography

References are to primary sources that you use in the text of your written work. A bibliography is a list of sources you have identified as useful (including references) but not necessarily used. The University will look very carefully at any references to see if you are prepared for study at Master's level in your chosen topic area. Overall, the expectation is that you will list at least 10 sources. For each source you must consider its:

Currency – looks at publication date and be aware of changes in technology. In technology books are soon dated.

Completeness – Make sure you are looking at the final version not some draft or abstract.

Uniqueness – is the source a primary one

Coverage – Use your list of sub-topics to ensure that you cover all the areas required so that you are fully prepared. But make sure that you are not including multiple texts with essentially the same content.

Range – Make sure you have a good range of authors.

Authority – ask is the text authoritative. This can be done by considering the author, publisher, writing style and currency. It is also possible to use citation indexes to see how often the source has been used.

Accuracy – Is the information correct? If you cannot be sure then you must not use it.

Relevance – Make sure that your sources are relevant to your project topic.

Usage - The basic usage strategy is:

Find – Relevant texts using a library index, the internet, online book stores and so on.

Evaluate – Once you find a possible source you must evaluate it for content and relevance.

Contextualise – that is fit this new source into your personal knowledge base.

Cite – If you use a source it must be listed in your reference section and cited in the text correctly.

Discuss – You may include something from a source in your work as a copy (quote), paraphrase or summary but in all cases you must introduce it, comment on it at cite its source.

5.6.4 Evaluating Internet Resources

When using internet resources it pays to be careful and always sceptical because of the following factors:

Anarchy - anyone can publish just about anything on the Internet

Validation - authors do not always have their materials checked by an authoritative third party

Tendentious – when the author wants to convince you of something and will use any means to do it.

Honesty - authors may not always be what they seem and may assume personas, lie or make false claims

Consider – the motives of those who publishing on the Internet

Trust - in research trust nothing until you have good cause to do so. This is the opposite of what we do in our daily lives in that we tend to trust until we have reason not to.

Context – be aware of the context of what you find. For example is it a University site, is it a manufacturer and so on.

Accuracy – this simply means is the information correct. You need to be aware that information might be validly collected but still be quite inaccurate.

Validity – this means that we ask is this a valid source in the sense that it was constructed in a reliable manner. Any lack of information on proof readers, editors and publishers means that mistakes are more prevalent than in print and therefore increased scope for innocent error and for outright deception.

Authority – this means was the author competent to create this material. For example any one could have an interest in say Emotional Intelligence and quite easily create an internet article on that subject but it would not have the same authority as that of a University professor who has spent years researching the topic.

Uniqueness – here we are asking is this an original work (a primary source)

Completeness – this may simply be described as asking if the work is the final and finished version. You need to be very careful here else you might find yourself using the material from the earlier part of the work which in fact was augmented at a later stage.

Coverage – this means what is the scope of the source. Now this does not mean that a source will cover everything on a given topic but it should be clear as to what it is covering.

5.7 Citation Examples

The following set of examples is intended to show some often poor use of citations and also some sound ones. These examples should be studied with care so that the flaws they illustrate may be avoided. The quotes are from a range of sources and topics and in your study of them you need to concentrate on the form. Now assume all the following were all written by the Research Methods tutor so the comments will be offered in the first person as if he is talking to you

These are just simple examples and they do not imply you must use italic or indenting as that is only used here to show clearly the pieces of work being looked at.

Example 1.

Lyau & Pucel (1995) found a link between training and productivity for their sample of Taiwanese car part manufacturers. Bartel (1994) found that training is a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors. Bishop (1994) and Barron, Black & Lowenstein (1989) both found that training increases management estimates of productivity.

This is poor because I only told you what the cited authors said. I did not introduce the author's words, nor discuss them and it's almost impossible for you to see what point I am making other than the obvious one that productivity and training may be linked – in effect it is not my work at all and there certainly is no sense of evaluation here. We might have written

Many authors (Lyau & Pucel 1995, Bartel, 1994, Barron, Black and Lowenstein 1989) found a link between training and productivity and that training is often a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors ... followed by your comments/discussion/analysis etc

Example 2

It has been found that because Arabic words were written by copyists who did not use vowels that over time the meaning of some words has been lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. One way to deal with this is to use assonance and in this paper that approach will be taken (Noldeke 2003, p45).

The problem is that it looks as if I attributed the entire paragraph to Noldeke. So you can have no idea which part of the paragraph was my own thought or maybe none of it was. This is bad practice and some tutors even regard it as blatant plagiarism. The fact is that tutors when they see this form in will automatically assume that all the student has done is paraphrase what he has found and none of it in effect is representative of any student thought and will mark the work down because of it. It could have been written as follows:

There has been a long standing problems with some early Arabic manuscripts in that many words have become obscure and even in context they are still unclear. Bigly and Ahmed (1978, p340) and others have shown conclusively that because Arabic words were often written by copyists who did not use vowel, over time the meaning of some words became lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. It has been usefully suggested by Noldeke (2003,p87) that one way to deal with this is to use "assonance analysis" to study word endings and in this paper that approach will be taken and in particular we will look at some early Arabic poems by Averroes.

You can use the bracketed form if you just want what amounts to passing reference to a source as in the following example.

In two recent works (Harding 1986a, p.80; 1986b, p.138) it has been suggested that ...

Example 3

St. Clair-Tisdall (1994, p45) said in his seminal paper on Organisation Synergy that "change in organisations is an inevitable consequence of growth" – this is an interesting observation and implies continuous IT progression and updating. Knowing this we can support Briggs (1999, p23) who said that OO is now routinely used in the computing industry.

This is poor because the first statement by St. Clair-Tisdal is clearly obvious and that by Briggs is common knowledge. Also it is not entirely clear that the second sentence leads logically from the first one. The point is that using citations here was unnecessary and therefore worthless. *We might have written.*

It is obvious change in organisations is an inevitable consequence of growth and in the modern world that must imply continuous IT progression and updating. Many authors, notably St Clair-Tisdall and Briggs have commented on how these naturally progressive elements may be factored usefully into a company overseas sales policy and....followed by your comments/discussion/analysis etc

Example 4

Suppose, in your reading you come across the following in a book by Noldeke. But the bit that interests you is by Frederickson – how will you set about properly using and referencing the Fredricksons quote?

Tools are needed if we are to measure software quality in a meaningful way. The idea of quality, as we know, is intangible since many views are possible. It follows that we must define some terms in order to measure quality. It is useful to note what Fredrickson said: "Definitions of what quantities we need to measure in order to assess software quality are at present arbitrary since as far as we know they have no connection with functionality".

This does not mean that they lack a rationale, but simply that professionals disagree on the definitions themselves and so it follows that

In this case the correct way is to find the Frederickson book and use that because it is the primary source. Quoting from secondary sources will only be tolerated in proven cases where the primary source cannot be found or for other reasons is inaccessible and it must be done in the correct manner as shown in Workbook 8 for secondary sources.

Example 5

Can you work out what the following extract from a piece of student work is saying?

It is argued that tacitness, complexity, and specificity in a company's skills and resources can generate causal ambiguity in competency-based advantage, and thus raise barriers to imitation (Fahey, 1989). This is to rise a company's distinctive strategic positioning so as to possess some form of sustainable competitive advantage.

The sentences is obviously copied as it is very, very unlikely that any student would write with such academic complexity and obscurity – lines like this are not designed to communicate they are designed to impress the reader not further his understanding. What it in fact it is saying is that some skills are very difficult to duplicate and this may mean that growth may be restricted. We might have written.

Fahey in his 1989 monograph has stated what should be obvious but he nevertheless less shows conclusively that companies often do not realize that some skills are very difficult to duplicate and this may mean that growth may be restricted or if you like it's not all that easy to copy a skill. ... followed by your comments/discussion/analysis etc

5.8 Literature Reviewing Cautions

Writing a literature review is a difficult and time consuming task if it is to be done well and there are no short cuts to sound scholarly work so here are some final pointers.

Justification - A literature review is NOT a justification for your research idea and such a review will never be regarded as explaining to the reader the topic area and your evaluation of it. Justifications often take the form of filling up the review with statistics but such an approach carries no real value in convincing the reader that you are master of that topic area.

Structure - It is very common to see students write down things in a literature review as they occur to them. This practice might be fine for notes but it is obvious that the way thoughts pop into ones mind or information is discovered is often anything but logical or structured. To communicate in writing effectively you must impose some structure on what you write else readers will not be able to see any progression in your thought or in the topic.

Pretence - some students try to be scholarly and pack their work with quotations and paraphrases – this then become not an evaluative review of what was found but a recitation of it instead. It is correct and desirable to tell your readers what you have uncovered but unless you make comments and add your own views on what is found the work will be regarded as a worthless recitation.

Non Review - some students just write down what they know without any references to the literature – this will always lose you marks as no one will believe that you obtained that information by your own brainpower without any outside assistance.

Experience – students often claim that what they write is all down to experiences but again no one will accept that. The way you use experience is in your evaluation of the sources, comments on them and building up your own arguments.

Inclusion – Preparation of the mind for your topic area does not mean you write down everything you know that might be relevant. What it does mean is being focused on your topic area and becoming expert in that. For example, an Engineering project where the literature review contains page after page devoted to telling the reader about every conceivable life cycle is hopeless and in such cases there is almost no thought over what is written and so it is worthless. Similarly, if a study project was looking at eCommerce as a way of selling drugs then page after page telling us about various drugs, treatments and prescribing practices is worthless in the context of just selling drugs. It's not volume is wanted but considered content.

Common Knowledge and Obvious - Quoting or paraphrasing material that is either obvious or common knowledge implies that you have not looked at the sources beyond the first page or forward. Here is an example from a project document. "Poston (2000) stated that organisation expected ERP systems to deliver improved performance". This is worthless as it is obvious that they would want this and to say it makes no valuable point at all - its no good trying to say things like this as if Poston was enunciating some law of the Universe or a point of huge importance on some new and valuable angle related to ERP - no he is just stating the obvious.

Bad Citations Style - It is very common to see the citation form (Briggs, 2000) placed at the end of a sentence or paragraph. This can ONLY mean that all you have done is paraphrased, summarised or copied that section. This practice is more or less plagiarism and is representative of a very lazy attitude that assumes that just expressing something in your own words is a valuable contribution - its is not because YOU are saying nothing and what you are supplying is not really your own work at all.

Activity Definition - Some students use the Literature Review to tell us what they are going to do in the research. This will result in a zero mark as what is to be done is covered in the Research Design so repeating it here is valueless. This practice is a certain sign of laziness.

6. WORKBOOK 6 – MAJOR PROJECT ELEMENTS

This workbook is intended to help students formulate clear project elements but here that what is said here is a mechanical process and it is your responsibility to make sure that what is written down makes sense.

6.1 Scope and Scale

Scope and scale are meant to be considered carefully otherwise a project which is out of control and way beyond your capabilities in the time available may occur. Alternatively, the scope and scale may be set so that the problem becomes trivial and the idea is rejected. So please take note of what these terms mean as far as this course is concerned.

Scope – this means something like selection or choice. So for example, if I were looking at training in desk-top packages I might select just Excel or I might select Excel and Access and so on to focus on. The point is I set my scope by being selective.

Scale – the means something like number or extent. So for example if I set my scope as looking at Excel I now need to set the number of users I will include in my study.

Scope and scale are two dimensions that set a frame around your work to bring it into sharp focus and exclude everything else. You need to put limits on both these dimensions but it is most important is to be clear about scope – that is, what exactly to include in your study, normally, just include ONE significant thing.

6.2 Presenting Problem

In any project it is usual to choose an area of knowledge and practice to be its topical focus. For example, one might choose modern usability issues, automated network management, digital paper and so on. Once one has a topic area it is necessary to choose one problem theme within it to be a sharp focus for a primary data research effort whose aim is problem resolution or partial resolution leading to a strategic business IT significant benefit. In general, it is not all that easy to give a simple and all embracing definition of the notion of problem but the following has proved to be useful.

A problem or issue is something that is a matter of concern or debate within the topic area and whose resolution might bring benefits. (Checkland 2003)

In practice this means a problem is an object not an activity. For example, stating the problem as “how to ride a bicycle” is incorrect since this is a question about the problem - the problem is “riding a bicycle”.

Another difficulty is that students often write down the problem in such a way that it is an answer or solution to the problem. So for example, if one writes a problem statement as “lack of training” then implicitly that is a solution as well. When this happens it is almost certain that the writer is not thinking about the problem at all but is obsessed with a particular solution. In this particular case the real problem might have been “errors in data entry” and one of many possible solutions is training.

6.2.1 Problems are Rarely Simple

It is easy to become blasé about defining a problem and this is often compounded by our desire to get to a solution as quick as possible – therefore I urge you to take care and thoroughly analyse the problem. There are perhaps three elements that need to be understood.

Reduction – it is desirable to simplify problems but that may also mean that you oversimplify and so one ends up with a very inadequate problem definition or model and of course if you do that your solution may fail in part or even totally.

Context – every problem exists in a context of some kind and we often call it “the problem situation” and if you are to have any chance of an adequate understanding and definition of the problem you must appreciate the context in which it exists. To give a simple example, on this course writing an adequate Research Question is problematic for students because the ideas will be new, they are working full time, they have family commitments and so on – these things affect your ability to get this work done. But for me writing a Research Question is relatively easy, because my context is different: I have experience in this area, I am retired so no work pressures to contend with, I don't have to worry about failing and so on.

Perspective – everyone has a different perspective on any given problem. For example at work you may see a particular problem one way but your manager may see it in quite a different light. Now, we cannot help taking a perspective but we can be aware of it and try to moderate its affect on the way we define the problem.

6.2.2 Defining the Problem

It is a good idea to construct one's own definition of the problem and to do it in as few words as possible. Notice, that it is your own definition not one you might look up in a book or on the internet (though you might start with that) because there is often little learning value in just copying a definition as far as deepening your own understanding is concerned.

Remember, that any definition one constructs will not be absolute and accepted by everyone - but in research this is not a problem as long as the researcher makes it clear what particular definition is being taken. Do not take this process too far and end up with either over-complicated or trivial definitions - they must be thoughtful and comprehensive. So it is recommended you start by thinking about six things where the acronym CCC-APE (stated as "triple C APE") is used:

- Characteristics** – observable features or facets of the problem idea,
- Context** – every problem exists in a context of some kind and it must be understood
- Causes** – every problem will arise due to some causes or causes
- Associations** – every problem will have links to other situation elements,
- Perspective** – when a problem is encountered it will always be from a certain perspective
- Effects** – say what effects ensue in the real world if the problem is not resolved.

6.2.3 Defining the Problem - Example

Let us suppose that a student has identified the problem theme as Phishing. Naturally, the student will be concerned that this is a good idea and would like confirmation of that before expending time on it. One can ask the course tutor, but he/she is not expert in everything so at best one would only get an opinion as a response so how should a researcher proceed. So for Phishing a researcher might note the following:

Characteristics: illegal, intrusive, upsetting, preys on those who trust their fellow man, etc

Context – phishing may occur at home or at work and in both these situations one naturally feels comfortable and secure and our systems may be well protected. However, that context can lull one into trusting the messages we get and it is exactly that element that the fraudsters want to exploit

Cause – it seems the cause is to do with greed or wanting to harm someone and feel, rather sickeningly, pleased in being successful at it. Notice an interesting thing here – mostly knowing the cause helps you to solve the problem but here most would say it's insoluble but possibly preventable.

Associations: email, chat, file sharing, etc.

Perspective: management (but try to look at it from several perspectives as well)

Effects: destroys confidences in the system, may lead to personal or company losses etc

Normally, it takes quite a few attempts before a definition that is lucid and comprehensive is obtained. Remember, the definition must also be useful within your research study – that is, it's no good having a well formed definition that does not offer a sound basis for a research effort.

Now here is a first attempt

In the modern world email is a technology that almost everyone uses whether in the home, at work, on the move and indeed it seems to follow one around. Typically, email is a simple one-to-one message passing technology but it is now offered with enhancements that include voice, video, chat, file passing, file sharing where suppliers are attempting to present a complete communication environments. With such a technology come problems and one such problem is identity theft and one way of getting this is known as Phishing. In its simple form an unknown, but apparently authentic, source asks for personal details and then uses them for fraudulent purposes. The problem is identity theft using email systems where a message poses as a legitimate requestor in order to fool the recipient into thinking it is legitimate request. The problem in computer system is known as Phishing.

Here is a final attempt (but most often there are several intermediate attempts)

Phishing is identity theft using email where a personal message seeks confidential or private information from its recipient whilst posing as legitimate request. The intention therefore is to fool the recipient into trusting the message and releasing information which can subsequently be used for fraudulent or other harmful purposes.

6.2.4 Cautions on Problem Definition

The acronym CCC-APE is just an aid to formulating a definition so one should not worry whether something is a characteristic or an effect - that does not matter very much because the whole idea is to uncover problem aspects and expand one's understanding of the problem theme.

As a very rough guide one often finds that the final definition must come down to about a third of what we start with. In most cases if one is familiar with the subject it is possible to create a good definition in about 1 to 2 hours and then if necessary update it as your project progresses as it is almost certain that there are elements that have been missed or imperfectly understood.

6.2.5 Problem Size

It is hard to measure the "size" of a problem because there is no scale on which to gauge it. But one can look at three aspects to get some idea.

Observable Effects – think about the effects of the existing problem and try to assess their seriousness in terms of the context in which it is set. In simple terms just ask "is it worth solving".

Causes – as was stated above, mostly knowing the cause helps you to solve the problem but some problems are so complex or so embedded in human nature that solution is impossible so in those cases we go for prevention.

Form of Answer – perhaps a better guide is to think about the form of answer and see how extensive, important and how hard it is to get. For example: one student wanted to deal with password overload – a clear problem with which we are all familiar but his outcome was a set of guidelines on how to construct good passwords but in my view that was a trivial answer to the problem because those guidelines can be found almost anywhere and it is doubtful if that goes anyway to solving the overload problem.

6.3 Project Target

When you think of a problem you normally do it in relation to its effects. It follows that you have to think very early in a project about what effects will be generated if you can resolve the problem – these real world effects are called the project target. Normally one settles on one major target although it is permissible to list more than one. Targets are effects so these are typically introduced by a verb form (increase, reduce, remove, reduce etc) and tend to be such things as: improved accuracy in data entry, to gain infrastructure resilience, streamlined workflow and so on.

6.4 Project Outcome

It is obvious that at the start of a project we do not have its outcome – but we can have some idea what its form may be. Therefore if we know our target we can speculate about what project outcome credibly might generate or go some way to generating the desirable target effects if used by situation actors. Outcomes are objects and so are typically expressed as nouns: Here are some examples:

The target of "improved accuracy in data entry" might be generated by a project outcome of a training needs assessment report or a training plan for use by departmental managers.

The target is "to gain infrastructure resilience" might be generated by a project outcome of a revised backbone design or a set of recommendations for new technology for use by the IT development team.

6.5 Situation Actors

Whenever you state an outcome you must always say who will use it (called the situation actors), how they will use it and hence show how the target effects are achieved. If you do not do this with care one often ends up with a worthless outcome because it is unusable or unsuitable.

6.6 Speculation

It is often useful when thinking about the solution to a problem theme to think of it as based around or generated by some personal theory a person holds about that problem and its setting. Essentially, one gets at this theory by speculating about causes and possible solutions routes. It is not easy to say how to speculate but it can be said that it is aided by a thorough literature review, personal experience and a deep consideration of the problem theme perceived in a given situation.

For example suppose the situation was related to issues with application software implementations in business not being as successful as expected. Recognition of this problem theme is a first step but if one is to do something about it, it might be useful to thoughtfully speculate on why success is lacking in this area. It follows that one might speculate that this lack of implementation success is due to poor implementation

strategies, or poor user training, or poor project management or any number of things. Notice that there will always be rival speculative ideas and that is why one must be thorough in looking at the literature and using your basic knowledge and experience to open up the problem situation in order to at least have a credible theory as to the most probable solution route otherwise one might just waste time on chasing nothing of value.

Do not let this idea run away – this is not about natural laws of the universe such as Ohms law or Archimedes Principle – here one tries to establish a personal belief about a situation and its problem theme. So after speculation one might express ones personal theory about the above example as follows.

It is believed that implementation of application software is proving difficult and this may be due to poor implementation strategies. It follows that if this is the case and better strategies can be defined then implementations may prove more useful in the future.

Notice that my theory points to a particular form of answer to this problem theme and in this case it is related to perhaps a document that explains how to formulate implementation strategies based on a consideration of user needs, application intention and business objectives. Occasionally, the theory may be embodied in a scientifically constructed hypothesis but more often than not in technological research it is expressed informally as an idea.

6.7 Primary Data

Primary Data is data is new data in the sense that it will not exist as a set until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data set is representative of some aspect of the area under investigation and can be processed to get a defined outcome that will resolve or partially resolve a stated problem theme when used by situation actors. All projects must be based on the collection and processing of primary data.

6.7.1 Primary Data Collection Protocol

Within every project there has to be a collection protocol for the practical collection of the primary data. Every complete protocol will have 5 features:

Vehicle – this is the primary mechanism or technique employed by the researcher, typical examples are: interview, questionnaire, observation, role playing, seminar, focus groups, document searching and so on

Recording Profile – this describes how the data will be physically recorded. Typically we might use: written report/transcripts, formatted record sheets, video, sound recording, computer logging, excerpts from documents and so on.

Sample criteria – this is a profile that allows the researcher to know that he/she has a valid sample point from which data is to be collected. For example, if we wanted data on business uses of Digital Paper we need a profile of who we should ask for that information. If we do not have a profile we may not have any consistency in our data and it may therefore be meaningless.

Permission – you have to feel certain that the information you seek is legitimately available to you.

Ethical Profile – you need to be clear as to what you are doing, the way you are doing it and what you are asking for is ethically acceptable. Two things are at stake: the results may be biased and the results may not be acceptable in the sense that they cannot be ethically used.

6.7.2 Project Purpose in a Nutshell

Students sometimes get confused over what a Master's project is about. Consider a topic area like Digital Paper which is likely to be a very hot technology in 2008. A Master's project is not about producing a long narrative on Digital Paper explaining what it is, how it is used and what the technological infrastructure to support it might be. A Master's project is about identifying a problem theme in Digital Paper and then collecting and processing primary data into a form that helps you resolve that problem theme based on ones own personal theory. With this in mind, consider the following examples.

Example 1. Suppose I want to define all the various accounting functions so I pick up a manual for my in-house accounting system and then go through it looking for all the various accounting functions and listing them – is that primary data and is this a valid research purpose? No because in the first place one might just regard the manual as listing the functions anyway so in effect the data already exists, secondly, this is just one book and so its content might be complex, trivial or totally unrepresentative.

Example 2. So if I extract (my basic activity) instances of phishing (my problem theme) from an email log that would be primary data because even though the email log (secondary data) obviously exists, the list of phishing instances (my primary data) as a set did not. My purpose being to process this collection of primary data to find out the most common sources of phishing and express my findings in an evaluatory report (my form of answer) to be used by my managers to eliminate or reduce successful phishing cases.

Example 3. If I conduct interviews in order to describe (my basic activity) a user purpose regarding illegal downloads (my problem theme) in my company with selected employees the interview transcripts are my raw primary data because the transcripts did not exist before the interviews took place. My purpose being to process this collection of primary data in order to develop a policy (my form of answer) to control illegal downloading activity for use by IT personnel in monitoring internet activity.

Example 4. If I look through written reports (secondary data) on security violations (my problem theme) for a particular company with a view to identifying (my basic activity) the root cause of each violation then even though the violation reports exist the list of root causes (my primary data) did not so it is primary data. My purpose being to process that collection of primary data to create a strategy (my form of answer) that will alleviate or remove certain kinds of violation in future when used by security managers.

Example 5. If I plan to build an application for processing student MSc marks (my problem theme) then I need to ascertain (my basic activity) the system requirements (my primary data). My purpose being to process this collection of primary data to create a design (my form of answer) for the marks processing system which can then be used by software developers to produce a working application.

6.7.3 Pre-processing Primary Raw Data

In many cases it will be necessary to process the raw data that one collects into a structured form of some kind so that is easier to use when generating the final project outcome. For example, if we have a series of interview transcripts it is obvious, that in that form, they are not easy to use so we might perform a pre-processing phase to get the core data into a more structured form that then constitutes our primary data set before the main processing phase that generates my project outcome is carried out. For example, suppose I examine company documents on misuse of IT system resources by employees. In this case I might proceed in two ways to get my structured primary data collection.

In line processing – that is I define my structure before I start and then as I come across a misuse example I structure it there and then. However, the disadvantage here is that you have to continually look back to see that you are not recoding the same data again and again from other incidents and so it tends to disrupt the collection process and make it longer to complete.

Pre-processing – here I wait until I have been through all the documents and then I use my set of notes to systematically work through the whole raw collection and form my structured collection that way.

6.8 Writing a Research Question (Study Projects)

This is intended to encapsulate your whole project idea and intention into one lucid question. Ideally one wants open questions that request information in the form of an answer. Questions can sometimes be like commands used to elicit a response and others such as "Would you pass the salt?" looks like a question but in fact is a request or action, not for an answer. In Research Methods, however we will only look for questions that elicit information.

The simplest questions implicitly or explicitly request information from a range (finite or infinite) of alternatives and these are often called bi-polar questions but more generally question ask for information that includes explanations, description and definitions. An interrogative word is a word used to start a question. All questions have a natural structure to them and that structure can change dramatically when you change the interrogative. In English the following is a list of interrogative words although some of them are rather old fashioned now.

Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, is/are, and can.

6.8.1 Questions that are not Questions

It is often difficult to write something that in English could be taken as a question. Now I am sure that in daily life everyone knows how to ask a question but when you write something down you are entering another world. Consider the following two lines – would they be understood as proper questions?

How to sharpen a pencil? Or What a pencil can do for you as a student?

Now these clearly ask for information but if you spoke these fragments to someone they would not quite see it as a proper question – in English such fragments would be understood as a kind of heading to a list of instructions for sharpening a pencil or a list of the benefits of using a pencil. That is that they imply that someone is giving you an answer not a question.

6.8.2 Basic Research Question Forms

It is best when attempting to construct a question to think about what sort of answer to expect – now in normal everyday life we do this instinctively. For example, you would not say “is this the right way to Pablo’s restaurant” if you wanted actual directions because that question form could only give you a Y/N answer. Instead you would probably say something like “how do I get to Pablo’s restaurant from here” and reasonably then you would expect an explanation. Broadly speaking there are four sorts of answer:

Bi-polar answers - Essentially questions that imply a limited range of possible answers. Typically, a bi-polar question starts with a word such as WHAT, IS, CAN or DOES.

- Is it possible to sharpen this pencil? (Y/N)
- Does it make sense to allow children to sharpen pencils (Y/N)
- Can a blue pencil be sharpened easily (Y/N)
- What is the common view of staff about using blue pencils? (Disagree, agree, etc)

Bi-polar questions can of course be useful but more often that not they have no great utility with forms such as “Can a green pencil be used in place of a red one?” Well of course it “can” be used so the answer is bound to be YES and so the question is pointless.

Explanatory answers – where the expected answer is an explanation and it is often in the form of a procedure or process. Typically, explanatory questions start with ‘HOW’ or ‘WHY’. For example, “How can a pencil be sharpened safely by young children?”

Descriptive answers – where the expected form of answer is a description most often in the form of an evaluation. Typically, these questions start with WHAT or WHY. For example, “What is the purpose of HB0 pencils?” (a simple explanation) or “Why are HB0 pencils difficult to sharpen?” (an evaluation)

Exploratory answers – where the expected form of answer implies an exploration of something. Typically, exploratory questions start with HOW or WHY. For example, “How should we use HB1 pencils best in drawing figures?” (often an exploration leads to an explanation)

The most common interrogative words to start questions are: what, where, would, in what way, can, is it, why, which, where, how, does, who, why and do – whatever word you use, always ask what form of answer is implied by each of them. You must be sure that whatever form you decide on as answer that you can actually construct it and when it is constructed as part of your research it is in fact useful strategically in some way.

For example, suppose I decide that the form of answer I want is “The role of technological innovation is business success”. The task you now have is to ask yourself whether you know how to express a role (write it down if you like) and whether knowing about this role will be of any use.

6.8.3 Research Question – Why are we asking it?

In normal everyday life questions come at us more or less all the time. Sometime we just answer them but more often that not we have a tendency to ask “why do you want to know”? It is therefore always useful when setting out your research question to ask why you asking it. That is you say to yourself, if I have the answer to this question then there will be some good outcome because of it. Sometimes we embed in our questions why we are asking them but mostly we do not. You will see later however, that you will have to make the reason plain in the aim so one might as well think it through at the question stage as well.

6.8.4 Research Question Form of Answer

For any Research Question there will always be several possible forms of answer arising out of ones personal theory about a problem situation encapsulated in the question. Ideally one would like the research question to be worded so that ONLY one form answer is possible and that is the one our theory suggested but often that is not easy to do so one normally has a range of options and competing theories to choose from so one looks for a form that interests you or looks to have the most utility. Do not be tempted to have multiple questions all in one sentence or look for multiple answers since it is better to focus on one significant output form. Table 4 lists the main forms of answer to help you when considering your personal theory.

Category	Typical Interrogatives	Expected Forms
Bi-polar	does, is, are, what, when or can	A list of possibilities
Explanations	how, why, who or where	A report, a model, an equation, a theory, a design, an evaluation etc
Explorations	How, who or what	A list, explanation, a comparison matrix, a pattern, a survey report, a theory etc
Descriptions	What, who or why	A report, a process or procedure, a model, a policy, a strategy, a theory etc
Table 3. Research Question Outcome Possibilities		

6.8.5 Strategy for formulating a Research Question

There is no easy way to do this and no real templates for it either so a good formulation will require some clear thinking and effort and that will show the examiners whether you are at Master's level or not in your thinking skills. A typical structure that you might use can be remembered by using the acronym IO-APTS. Therefore the IO-APTS elements are:

Interrogative – what is your key interrogative word (how, why, what etc). You should note that some interrogatives need to use two words if a proper question is to be formed. For example, “how” on its own will not normally make a question but when you say “how can” it is clearly a question.

Outcome – here one asks what sort of answer and what form it might take. Answers might be yes/no, an explanation, an exploration, a description which may be expressed at the end of the project as a report, a model, a list and so on.

Actor – the person or persons who take the outcome and use it to get the target effects

Problem – focusing on a single significant problem and be as concise as you can.

Target – what effects will be observable and measurable in the real world if you can resolve the problem. Effects are things such as efficiency gains, provide or enable better communication, increased accuracy and so on.

Spotlight – put the spotlight on where the primary data or information needed to answer the question might help come from.

Generally, the Research Question should ask always about the outcome and who will use it to solve the problem to get the target effects. However, the order in which the question features go in the sentence is largely governed by the interrogative used. It follows that it is possible to write the question in several ways depending on the interrogative used. The interrogative “what” is often used and then a good question seems to use the features in the order: Interrogative, outcome, actors, problem, target and spotlight. Here is a student work example:

What (**interrogative**) portfolio of accounting best practices (**outcome**) can be identified for use by junior personnel (**actors**) to avoid billing delays (**problem**) in order to improve the quality of response to customers (**target**) based on an examination of the initial accounting processes stages (**spotlight**)?

I used “what” here because I am looking for a process and this interrogative seem very appropriate for that kind of outcome form. Depending in what we want we might end up with a different interrogative and a different question format. Suppose we did not want to find the best practices but just explain why the current ones do not work then we might write the following but as you can see we get a slightly awkward sort of construction when we try to add the outcome and the actors.

Why (**interrogative**) is the current portfolio of accounting best practices (**spotlight**) as used by junior personnel creating long billing delays and poor quality customer response, (**problem**) expressed as an evaluation report (**outcome**) for use by application consultants (**actors**) to ensure there is an informed (**target**) management personnel on possible process changes.

Whatever interrogative you use you must always fit in the 6 features to make it comprehensive and this will often require a little ingenuity. One very common error that you must guard against is asking how the outcome can be used because in most cases it is obvious. To use a trivial example, one often sees questions that say things like “How can I use my training as a driver to drive a car?”

6.8.6 Meaning in a Research Question

This section has looked at the structure of a typical Research Question but it **MUST** be thought out step by step and even then one has to think does it make any sense, is it a focused question, what sort of answer should I expect and so on – there is simply no substitute for careful thinking.

Once you have formulated your research question and have a good idea what form the answer will take then its time to test it using the following ideas. Now be aware that this is just a test of structure and of itself it does not mean the question makes sense – there is no way to do that other than using your own brainpower and common sense – if it makes sense to you it will probably make sense to whoever else looks at it.

English – does it read correctly in English as a question?

Paraphrase – if it's a good question you may be able to ask it in several different ways – so try to do that until you get a formulation, perhaps with a different interrogative, until you are happy with.

Bi-polar – this means that the question has a fixed and limited range of answers such as “Y/N”, “bad”, “good”, and “excellent”. This type of question can of course be useful but the problem with them is that such answers do not have much utility – that is they do not tell you anything of value in terms of what action or actions you might take. You are advised to avoid such questions for your project.

Discussion – look at your question and honestly ask ‘will this question produce discussion?’ – what this means is to ask ‘who am I writing this question for and would it interest them’. Try not to think that you are doing this for your Research Methods tutor but try to think what you would do if you were trying to get funding for research to get an answer to the question from someone.

Answer Form – try to work out what form or forms the answer will take (typically: bi-polar, explanation, description or an exploration) – if you try to avoid this aspect you may find yourself in serious trouble with your research.

6.8.7 Common Errors in Research Questions

The following are typical errors found in student written Research Questions – they can all be avoided if one takes just a minute to think through what has been asked and what sort of answer is likely.

Not a Question - to an English speaker the following would not sound like a question, instead it would sound like a heading to a list of instructions or a procedure. "How to make business application development productive at XYZ Corporation?"

Multiple Questions – It is never a good idea to try to put TWO (or more) questions into one as in the following example - one is about testing and one is about bugs they are quite different things. "How can software bugs be minimised and the testing cycle shortened in the development process of an Inventory System?"

Obvious Answer – these are cases when no research is needed because the answer is either obvious or common knowledge. Questions like this show a serious lack of thought – take the second example below and it is easy to see that the answer to the question is bound to be YES - of course a productive work-life balance "CAN" (but might not) be obtained so there is nothing of any value whatsoever in a question like this. Similarly, it is easy to explain how a better development process can increase productivity.

"How can a better business application development process increase the productivity at XYZ?" or

"Can a productive work-life balance be achieved with telecommuting for technical personnel?"

No clarity about each IO-APTS feature - I would recommend that you add in brackets the 6 feature names as I have done above when you write your question.

Each IO-APTS feature occurs once - this is important because it's again all about being clear what each feature is and helping the reader understand what it is you have written.

IO-APTS features in some cases may be combined - you may do this if the question sounds more natural to you but be careful that you really do know what each feature is.

Confusion with target and problem - this is often caused because a student gets muddled up about the effects wanted and what the actual problem is. Again when we see this it makes us wonder if you have understood the very basis of your own project idea.

Confusion over target and outcome – this is perhaps the most serious error and it would imply that you do not understand the most basic distinction.

Please remember that it is possible to write a very poor question that exhibits more than just one error type and yet has all the required features - there is simply no substitute for thinking about what it is you have written.

6.9 Primary Data Generation with Activity and Spotlight

Based on a problem theme, theory and the form of the project outcome expected one needs to formulate a process to create a structured collection of primary data. There is no algorithm for doing this and one has to go carefully through the steps: define the data, locate the data and decide on a protocol to collect that data reliably.

Activity – this is also known as a Basic Activity for Generating Data (BAGeD). All it means is that one has to do something (an activity) to get the data and these activities must inform you how to write down the data. Possible activities might be: account for, collate, assess, profile, illustrate and so on. Notice that activities like “interview” are of no value here because they don’t tell us what to do with the data. That is we can say “profile the inventory management staff” because it tells us what to record as data (profiles) but although we can say “interview the inventory management staff” we now have no idea what data we are looking for.

It is an idea if the activity is just one verb and list of useful verbs can be found in Workbook 16. One needs to be careful here that the activity is clear since almost all verbs need to be qualified or supported by stating their object. For example, if I were to say, “look at fault logs for my primary data” then that is very indistinct because it does not tell us what to look for (the object of the looking). But if I say, “look at fault logs to describe instances of SPAM attacks” then I now have a more distinct activity because I know what I am going to write down as my primary data. The whole primary data collection process is then fitted around that basic activity and the spotlight described below.

Primary Data Spotlight - The core of this primary data generation process is to find an activity which we can use to extract data and coupled with that we must have a primary data spotlight (usually we just say spotlight) that is focused and illuminates just the primary data that you want.

As an example, suppose the problem theme is the value of IT training. Clearly a lot of money is spent on training so it might be really useful to know if there is a link between it and productivity. Suppose we speculate that the link is to do with essential business working practices and these change over time to meet new needs so that what I need is an outcome in the form of a process model on how one identifies changes in business essential working practices and links them to a training initiative.

Now that I have my outcome as a process model the activity (BAGeD) can become **describe changes in essential working practices** of key operational staff – thus, my activity is “**describe**” and the primary data spotlight will be **changes in essential working practices**. Now that I have this core activity and spotlight I can work out the full process of getting to the data and processing the resultant collection to get my process model (outcome) that describes the link between business essential working practices and training.

Once the activity and spotlight are clear it is an easy step to say how that data will be collected. In the above example I might use interviews with relevant staff. In summary the whole process becomes **describe** (activity) **changes in essential working practices** (spotlight) using **interviewing** (collection protocol) with relevant staff.

6.10 Getting an Activity and Primary Data Spotlight

This can be quite hard to do but it is essential to find this activity and spotlight. So we are looking for an activity and we hope that activity can be used with the spotlighted data. There are only three real considerations:

Problem Area Expertise – it is obvious that you need to have gained expert knowledge in the topic area and in the particular aspect related to the problem theme you are dealing with. Unless you have thoroughly prepared by using literature reviews and/or other means you will simply not be in a position to know enough to be able to decide competently what data it is possible to collect.

Intended Outcome – fix in your mind that you are trying to generate as an outcome and recall that whatever primary data you collect will be first formed into a structured collection during the pre-processing phase, which follows immediately after collection, and then that structured collection will be used to generate, in some defined manner, your outcome.

Let us suppose the outcome is to be a set of guidelines, so you have to think what sort of primary data is needed to be able to generate the guidelines and that might be to look at current practices. Once we have the data on current practices we can move on to finding out how to generate guidelines from that data. This means you must know what a guideline is and how one is constructed and that is where secondary data comes in. So in this case you might look at text books or journal articles to find a guideline model to use. Additionally, you would look at examples as well as look at any relevant company or international standards.

Collection Protocol – the last thing to consider is can the primary data be collected and if it so, what is the best way to do that. So it's not a matter of just choosing anything that comes to hand, it is a serious practical consideration based on a thorough and logical analysis of the sort of primary data that you want.

In the guidelines example above, the idea might be to use a questionnaire and one has to ask would a questionnaire allow for the collection of the data I needed. Let us suppose that the data we spotlight is related to finding guidelines for IT media and usage. Now a questionnaire can easily get media data but it is not clear how it could capture usage data so I might decide to get that information by interview instead because I want a richer picture there - guidelines are largely about usage so that is where I must direct my effort.

To elaborate, usage is a complex issue and if you try to get it with a questionnaire you must have a very good idea what the usage processes are otherwise you may miss lots of things that are going on in the company setting. Whereas, if I use an interview, I have much more opportunity to explore the usage idea and that is what I really want.

6.11 Problem, Outcome, Activity and Spotlight Examples

Consider the following further examples which focus on the activity and data spotlight and its link with some theorising or speculation about an expected project outcome. In each case several possible outcomes are listed but in a research study only one would be chosen for further work.

One needs to be careful – this all sounds fine, even simple but a researcher must seriously consider if a complete process built around the activity and spotlight can be formulated in order to get at the necessary primary data within the time and other resources that are available.

Problem - Loss of competitiveness in Hong Kong SMEs

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A list and description of investment constraints or
- A strategy to deal with the investment constraints or
- A feasibility report on e-application implementation or
- A post implementation review report or
- A prediction reacted to the effects of the constraints

Let us suppose that I choose a list and description as my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on reviewing (activity) investment plans and the corresponding strategic plan in order to describe (spotlight) an investment constraint (Generated Primary Data). So my primary data will consist of a list of identified and defined investment constraints.

Problem – Data losses associated with non-effective IT business systems

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A process of data criticality categorisations or
- A user guide to data criticality or
- A DRP/BCP policy document or
- A report explaining how data and criticality are related

Let us suppose that I choose a DRP/BCP policy document my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on listing data categories and using these categories I review reported critical incidents related to data categories (spotlight) in order to match (activity) the category to the criticality of the incident (Generated Primary Data). So my primary data will consist of a list of categorised critical incidents.

Problem - Supplies continuity in manufacturing systems

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A evaluation of a modern supply change process or
- A feasibility report on RFID or
- An implementation plan for RFID or
- A model that shows how improvements may be made using RFID

Let us suppose that I choose to list and describe expected benefits of RFID as my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on describing (activity) supply chain (spotlight) tracking problems (generated primary data) and by a process of evaluation of each problem theme I suggest how it might be alleviated by RFID and hence an implied supply chain benefit. So my primary data will consist of a list of categorised problem themes in supply chain tracking.

Problem - Business productivity in sales staff

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A feasibility study on IM and its use in offices or
- The definition of a training programme or
- A series of factors that must be in place before IM adoption or
- A cost/benefits report on Instant Messaging Technologies or
- The design of a regular monitoring scheme to assess effectiveness

Let us suppose that I choose a cost/benefit report as my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on analysing (activity) call content (spotlight) to identify the sort or calls and then extract the cost (generated primary data) and assess the sales benefit and by process of evaluation arrive at my cost/benefit report on IM technology. So my primary data will consist of a list of calls and their associated cost and sales benefit.

6.12 Writing an Hypothesis

Hypotheses are not always needed but if used they must match your research question and amounts to you saying what you think to be true in a given situation. When you do this your work then become a process whereby you try to show that your hypothesis is valid. There are three stages: firstly write the null hypothesis, secondly write the alternative hypothesis and lastly write down the dependant and independent variables. Unfortunately many new researchers seem unable to do the last part of this process. Let me illustrate.

A student wanted to write a hypothesis that essentially said that there was a link between IT certification training and personal productivity in support roles. He then went on to define the variables as: Role of IT (independent) and Personal Productivity (Dependent). Now this will ONLY makes sense if you can quantify the variables productivity (which is quite easy) and 'Role of IT' which it seems cannot be quantified.

In research people tend to treat the idea of hypothesis in two ways and the second way is often quite valuable in many research situations.

6.12.1 Formal Experiment

To set up a formal experiment one creates or identifies two samples: one exposed to some effect and one not. For example, suppose I were looking at whether a new diet called lose-weight-quick worked or not. I could set it up a hypothesis and look for samples where some people were exposed to the new diet and some were who were not. The experiment then amounts to seeing if there is any significant difference between these two samples. (See CN.001 Notes for how to set up a formal hypothesis)

In a sense we are trying to prove the diet works but that notion of proof needs very careful understanding. The point is that it is very likely that the diet will work for some in the sample and not for others. So our proof carries a qualification which is that all we could reasonably say at the end is that the diet is likely to work for a large number of people (or not as the case may be). A second point is that we do not usually do thousands of

similar experiments and so at best our results for a limited sample would be tentative. Notice that this outcome is quite different from an experiment that sets out to verify a natural law like Archimedes principle or Ohms law where the amount of variety is much, much less and of course such natural laws have been tested many thousands of times so we are assured of their validity.

Strictly, proof means that something is true for everyone, for all time and everywhere and it is obvious that that kind of proof is very hard to construct in technology. What we therefore tend to do is not to use the word proof but rather say that our research “indicates” that something is generally true. So for example, it is impossible to prove (for everyone, everywhere and for all time) that CRM system bring productivity benefits at low cost but our research might be able to indicate that this is often the case for those who use it.

6.12.2 Informal Idea

Instead of using a formal null hypothesis we could just have what might be called a tentative hypothesis that suggests that there may be a link and then use case studies, surveys, quasi-experiments and so on to demonstrate this. Notice that we are NOT proving anything here only suggesting that something may be generally true within certain parameters.

6.13 Writing an Aim and Objectives

For each project we want one overall aim and a set of objectives that collectively will generate the project outcome. An aim/objective is expressed as an activity to get a defined and measurable outcome within the scope of the project. The essential difference is that the aim expresses the target (or purpose) for the whole project outcome whilst objectives generate minor project outcomes that collectively allow us to eventually generate the project outcome and hence achieve the target.

6.13.1 Project Aim

This derives from the Research Question and is best thought of as expressing the overall activity and intention of the project to generate an outcome that can be placed in the project document or made easily visible to the examiners.

You will note in the aim structure that follows that the problem theme is not usually explicitly mentioned and we infer what it is by looking at the target. The reason it is not included explicitly is that when one does one tends to get very awkward constructions linking problem and target so we might see absurdities such as “to improve website accessibility because web site accessibility is problematic”.

The most common aim structure is as follows where project outcome is its most essential part because this is what the whole project effort is intended to generate. The structure can be remembered by using the acronym AOST.

Activity – what principal activity will be used with the available data to get the project outcome? Ideally, look for a single activity that sums up the whole project process for generating the intended outcome.

Outcome – this element says how the project outcome will be expressed knowing that this outcome will later be used to generate the real world target. What ever you say here **MUST** match with whatever outcome you state everywhere else in your specification.

Spotlight – where will the basic data used by the activity come from?

Target – what is the real world intention? That is the project outcome should be useful in the sense that it addresses the real world problem theme on which the project is based.

Aim – to create (**activity**) a website structure design (**outcome**) using cascading style sheets (**spotlight**) in order that it might be used in design to improve web site accessibility (**target**).

Sample Faulty Aim 1 – “To create an improved network infrastructure”. This is unsatisfactory because we have no target - we know that there will be an improved infrastructure but we don't know what effects that will have. So is improved infrastructure the outcome – it cannot be because it would imply sending to Portsmouth for marking some object called “improved infrastructure” and that is an absurdity. So here we have no target and no outcome and we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

So if I just use the above example it would be possible to have a target of a reduced network down time because of the Improved network infrastructure but that could **ONLY** happen after the project completes and in the project one could generate an infrastructure design - now that can be completed within the

project period and later used to build the infrastructure which can then be used to generate our reduced network down time. Another factor here is that we cannot measure whether something called improved network infrastructure (what scale would we use?) has been achieved unless we have a target such as reduced down time which of course we can measure.

Sample Faulty Aim 2 – “To build a Wi-Fi implementation strategy”. This is unsatisfactory because although we know the project outcome is an implementation strategy we do not know what value it has in the real world because we have no target. Notice also we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

6.13.2 Project Objectives

The aim expresses the project outcome but to get there we normally have to pass through a number of minor outcome milestones on the way and these are expressed as being generated by objectives. Since we are looking for minor project outcomes milestones that collectively deliver the project outcome we have a little problem here because any project is made up of a series of tasks from generating page footer to evaluating the project outcome. It follows that some tasks will generate a minor project outcome and some will not.

Objectives are not the same as making a project plan because they are ONLY concerned with activities that generate a minor project outcome - a schedule of interviews is a project activity but that schedule can hardly be regarded as a project outcome, it is just a step along the way to getting the primary data – so one might add that into the project plan but it would not be written as objective.

The structure and features expected in a well-written objective are as follows where you can use the acronym AMSB.

Activity – Ideally we look for the principal activity that will generate a minor project outcome that can be expressed in a form that can appear in the project document.

Milestone – in this feature you state the milestone as a minor outcome, knowing that it must be in a form that can be written into the project document and represent a sequential step building toward getting the final project outcome.

Spotlight – what is the data area focus of the objective's activity?

Bounded - objective outcomes must be achieved and available within the project period and must not refer to anything that might occur after the project document is completed and submitted

Example – To explore (**activity**) and model (**milestone**) the current software development process (**spotlight**).

This is **bounded** because we can do it within the project period and it is also a **milestone** (building block if you like) leading to my project outcome of a best practice portfolio in software construction.

It is easy to become completely muddled with objectives and one source of this muddle is the distinction between a project objective: something that a student can do and evidence in the project document and operational ones: something that has a real world effect that might happen after the project has been completed. In simple terms if you set an objective in your project it must be completed within the project time scale. Let us just take an aim and look at some possible objectives.

Aim = To survey (**activity**) workers in Southampton (**spotlight**) and report (**outcome**) on how they use the bicycle as an aid to mobility (**target**) in a modern urban environment.

Sample Objective 1 – “To identify and list (**activity**) in a report (**milestone**) the components of a modern bicycle (**spotlight**)”. This is fine since clearly it is something that you can do, evidence in a project document so somebody else could check what you have done and it is clearly bounded.

Sample Objective 2 – “To describe (**activity**) how a bicycle functions”. This is no good since although it is clear that you can develop a description, no one can check it unless you write it down and it is not clear where we would look for the data. Better to say “To describe (**activity**) by means of annotated diagrams (**milestone**) how a bicycle functions by observing it in use (**spotlight**)”

Sample Objective 3 – “To understand (**activity**) how a bicycle helps urban workers (**spotlight**)”. This is no good because there is no clear spotlight so there is nothing to focus ones understanding on and even if

there were no one else can check your understanding because there is no milestone. Better to say, "To prepare (activity) a report (milestone) explaining how urban workers could be helped by the use of a bicycle in their daily lives by examining typical patterns of mobility for office workers in Southampton".

Sample Objective 4 - "To ensure (activity) that workers get to their office on time by using a bicycle". This is no good because there is no way anyone could do this activity and if you cannot do it no one can check what you have done. It also sounds more like an aim than an objective because it hints at a target. Better to say "To report (activity) on bicycle usage strategies (milestone) that might be applied by urban workers to ensure they get to work on time by identifying and observing regular cyclist's usage profiles".

Sample Objective 5 - "To implement (activity) a bicycle repair system". This is no good because although it is obvious you can do it, it cannot be checked in your project document because it is an operational activity and not a milestone that can be documented. But you could say "To produce (activity) a design document (milestone) for the creation of a bicycle repair centre by examining manufactures basic requirements for business applications of this nature (spotlight)".

Sample Objective 6 - "To ensure (activity) that bicycles conform to BS 7898 (spotlight)". This is not really much good as it is in essence a requirement and not something that one can do within a project itself. However, one might have written "To evaluate (activity) and report on infrastructures (milestone) necessary to achieve BS 7898 compliance requirements (spotlight)".

6.14 Writing a Title

The title is the name of your project – rather like the name of a novel, something that catches a potential reader's attention but just gives a hint as to what the work is all about. Think of it as a kind of nickname or slogan for your project and as such it is not a good idea to try to use the same set of words for the title, Research Question and aim. Titles typically have two elements:

Aspect – this is the particular focused area of you study

Why – this says why it might be a useful aspect

Mentioning the means by which you solved your problem should only be included in the title if it is crucially important. As an example, suppose your project was concerned with the development of a database and you used Microsoft Access. Unless your project compared your product with a similar database implemented in Oracle, say, then the tool you used to solve the problem is not as important as the problem you set out to solve.

Be careful with titles, there is a tendency to use the title to say what you will do. The purpose of the title is to give a concise name to what you do. Avoid noise words or phrases such as: "A report into..." (redundant: of course it is a report!) or words like "study", "investigation", "enquiry" and "development" are often similarly just noise. It is also usually very unwise to express the title of your project as a question although a title in the form of a proposition is often quite useful as in example 1 below. Here are some examples of good titles:

Planar Similarity – A Possible Software Quality Measure
Heuristics in the Stages of Soft Systems Methodology
A Taxonomy of Heuristic Problem Solving

7. WORKBOOK 7 – BASIC RESEARCH METHODS CHECKLIST

The work book is all about being able to select a research/problem solving method that fits the sort of research study you are engaged in. In every case you will have to decide what data you want to collect and choose rationally a research method (problem solving method if you like) as your primary research vehicle and build a research design around it.

You need to exercise care here so as not to become confused between a Research Method, which is a framework or model for the whole research project such as survey or action research, and Data Collection Protocols, which are vehicles for actually collecting the primary data and might include such things as interview, observation, questionnaire, seminar or role playing. However, before looking at these research models it is useful to just review basic research styles and approaches.

7.1 Research Styles

This is a practical notion and you would be wise to think project ideas through in terms of these styles. There is no sense that one or other is superior and no reason why both should not be applied at the same time.

Quantitative – a style that represents information in numerical form. The numerical form might be graphs and statistics which can be used to show trends, comparison and similarities and the graphs might lead to equations which link variables or allow one to make generalisations.

The advantage of quantitative data is that there is solid evidence that can be permuted in a variety of ways to support or not support a contention. In general, one is counting the frequency of some event – say the number of times the user selects the wrong icon but, and it's a big but, the data is only truly valid in the context in which it was collected so one needs extreme care if we want to generalise.

Qualitative – a style typically used to analyse how certain actions occur not just how often they occur. The information is usually represented in textual form of some kind as a description of some observable event or events. The usefulness of this is that it exposes the thought processes or reasoning behind a particular behaviour – why a user clicked the wrong icon. However, it does make the analysis and representation of the data more complex.

Although these are defined, in practice one does not usually start by thinking about the style and typically as you think about the problem and what primary data your research will collect to deal with it then it tends to define itself as predominantly quantitative or qualitative.

7.2 Research Approaches

There are two broad approaches to research, which is always essentially exploratory. In practice you do not decide the approach as such and it will effectively be decided for you when you formulate your research problem and construct your research design. However, we may loosely define:

Deduction - This means inferring particular instances from a general law. So if for example we use Ohm's law to predict with certainty the value of current if we know the resistance and voltage applied to a circuit. In technology I might want to look at the significance of scripting languages on system development time. I could do this by setting up a null hypothesis that says 'I contend that the use of scripting languages have no effect on system development time' so in effect I am suggesting a law here.

Inductive - This means the inference of a general law from the observations of particular instances. For example, you notice something that happens and see that it happens often. It follows that you can infer a general law from your observations. For example, you notice that people in your company tend to be more productive after IT training so you then make a generalisation using induction and say "training in IT leads to personal productivity increase".

It is very important you understand that nothing has been proved here and all you have is an indication. It is not a proof because we cannot know what new tasks or technologies might occur in the future. One of the greatest modern philosophers, Popper, put it like this. "you can never accurately predict the future because it is impossible for men to know now what they, or others men, will know in the future". It follows that we are never possessed of the data that can allow us to make certain predictions about what may lie over the horizon based on our current stock of knowledge.

In research we might think along either of these lines so for example we often set a hypothesis (a guess at general law) and then try to prove it. Alternatively we can go and collect data and by looking at the data see if we can work out what the law involved might be.

There is no right/wrong approach and it's a matter for you to consider what sort of outlook you are taking although in technology we tend to take an inductive attitude. It may sound simple and often no matter what our stance we end up collecting the same data but it will not always be simple – supposed you were looking at the effects of system migration in a rapidly expanding company and project control methods then it is not obvious what the link between these two things might be so a deductive stance would be unsuitable here.

7.3 Research Outlook

Before we look at the various research methods it is useful just to records that there are two outlooks that are available to a researchers.

Hypothesis Driven – this is the classical research paradigm where we have by some means devised a theory or speculation of some kind and the research is then directed at trying to show that the theory or speculation is valid. For example, we might theorise about who buys Gel Pens and then try to show that it is true, or more usefully try to explain in a report why it is true

Data Driven – it often happens that when we embark on research we don't have a hypothesis which we are setting out to test. This is very common today where corporations have vast databases and want to see if there is anything useful in them that might for example lead to competitive advantage. It follows, that in these cases we don't start with a hypothesis but we examine the data sets looking for patterns or outliers or indeed anything that might allow us to formulate a theory of some kind. For example, we might look through millions of sales transactions and then to hypothesise that people who buy Gel Pens all have beards and wear dark glasses. If this theory is true we can better target our Gel Pen products.

7.4 Which Research/Problem Method to Use?

There are many methods/models that we use for setting up research, the most common being: case studies, vignettes, action research, experiments, surveys, biographies/histories, grounded theory, ethnography and requirements gathering. It is never easy to decide on a method or perhaps more than one method.

Usually in research we do such things as: understand, explore, describe, explain, illustrate, improve, build something or prove something. It is therefore very important when you are trying to decide on a method to keep this basic purpose uppermost in your mind.

Choosing a research/problem method will depend on many factors such as: context, available literature base, basic research purpose, is the domain changing rapidly, time available, skill available, sampling and other practicalities, access, your personal stylistic inclinations, reason for the study, what kind of outcome you want, cost, quantitative/qualitative, scale, control, sensitivity of the data and so on. Notice these factors are almost all about practicalities - a design has to be used and that means it has to be practical.

7.5 Rationale: Case Studies

The case study method focuses on just one, two or twenty examples – such as your place of work, or one element of your organization or several aspects of a problem area. Typically:

1. Case studies are commonly used to **illustrate** or **understand** a problem or **indicate** good practice.
2. Case studies always have a context so make sure you are aware of it.
3. Case studies are usually qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain or describe some activity or phenomena.
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. There are broadly speaking two ways to begin case studies. This first is that you can set criteria and then go looking for relevant cases or secondly you can design and create the cases.
7. For most case studies there is usually be a longitudinal element - that is the cases will run over a fixed time period and you will periodically visit each case to collect the data.
8. There are several kinds of case possible:

Unique – implying that the setting and context are extremely rare and there may not be another chance to study this problem area again.

Critical – implies an important theory that you want to test and a particular case fits that profile.

Representative – implies that the case profile represents a typical or everyday situation.

Revelatory – implies that the case profile allows a researcher to study a situation never before looked at in detail and its context may be common.

9. In practice you can use the following to organise your cases but remember once you have your case design you will need permission from whoever is necessary.

How many cases – be practical because there are time limits.

Case Criteria - add as many criteria as you think necessary to pin down the data location but don't have so many that you will never find a case that fits.

Sample criteria (collection protocol) – add as many criteria as you need to pin down a particular sample point where a unit of data can be obtained.

Visit Frequency - each case must be visited to get the data so work this out by looking at how much total time is available for the study.

Data collection Vehicle – by observation, interview, document analysis, etc. You will have to have a protocol to say when a valid sample arrives.

7.6 Rationale: Vignettes

These are perhaps best thought of as micro case studies or snapshots that illustrate just one idea and almost always are qualitative in their application. Typically:

1. Vignettes are commonly used in research contexts where actions, motives and judgements are to be explored, often in sensitive situations and you want to extract and **describe** examples or **illustrations** of significant elements in that problem domain
2. Vignettes always have a context so make sure you are aware of it.
3. Vignettes are essentially qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain, test an idea or describe some activity or phenomena.
5. Typically you cannot control and indeed have no desire to control the events being looked at but the events should be contemporary.
6. Vignettes enable participants to define the situation in their own terms or for their needs.
7. Most vignettes are "one off" events and as such act as indicators of an idea rather than as some sort of proof of concept. Therefore, this may also be useful when only a small sample is possible.

7.7 Rationale: Action Research

The main purpose of action research is to improve identified practice in some way. Typically:

1. Action research is commonly used to conduct research at the workplace with a strong desire to **improving** aspects of your own or colleagues' work so
2. In this kind of research you must be in control of events and they must be contemporary.
3. Typically indicated as useful when the research question starts with 'how' and there is a desire to explain something and use that explanation to improve practice.
4. Because of its setting, it is obvious that the research design is linked closely to its context.
5. The whole point of doing action research is the research leads to change in practice.
6. The working strategy is: plan something, do something, observe the something and reflect on what has happened as a result of your actions.

7.8 Rationale: Experiments

This form of research is used where there is a hypothesis and an associated variable that you can control (the independent variable) that will produce a change in some other variable (the dependent variable). That is the whole idea implies that you can intervene by altering or controlling the independent variable. Typically:

1. Experiments are commonly used when you want to **prove** or at least **indicate** that something is true. In practice proof is very difficult as it would imply that you findings are true for everyone, everywhere and for all time and so then tendency is to say indicate rather than prove in most cases.
2. In very simple terms one forms two groups: one which is exposed to the intervention and one which is not and then we observe if there is any difference because of the intervention.
3. Typically indicated when the research question starts with 'how' or 'why'.
4. The researchers must be in control of the events being looked at and they must be contemporary
5. The biggest risk is that there may be other variables involved which we are not aware of.
6. It is difficult to be sure that our sample is representative.

7.9 Rationale: Quasi-Experiments

This form of research is used where there is a hypothesis and associated variables but you cannot control any of them. It would be nice to think we always had time and resources to run a carefully designed experiment but unfortunately this is often not the case. In an experimental design one chooses the samples involved randomly and thus one has control. However, it may be that data already exists and you can test your theory on that existing data or it may be that you simply cannot get control over all the variables that you want. So an experiment and a quasi-experiment are very similar it's just that the quasi-experiment does not quite have all the trappings that a full experiment has.

7.10 Rationale: Surveys

This form of research is used when we want to ask a group of people a question or questions. Typically:

1. Surveys are commonly used when one needs to get and express an overall **understanding** of the properties in a given domain.
2. One could of course also survey 'things' as well as people.
3. Surveys lend themselves to future replication.
4. Typically indicated when the research question starts with 'who', 'what', 'where', 'how' many' and 'how much'
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. Questions must be well-designed and unbiased and may be asked by interview or questionnaire.
7. Be careful to distinguish questions that are asking for facts and questions that are asking for opinion
8. The results will be very dependant on having a big enough and representative sample.
9. Be clear as to how the data will be collected – by observation, interview, questionnaire, etc. You will have to have a protocol to say when a valid sample arrives.

7.11 Rationale: Biographies/History

This form of research is used when we want to trace an historical event and analyses/evaluate its history as this may lead to insights or explain certain action so that lessons may be learned.

1. Biographies/History are commonly used to form a **description** and **explanation** of events.
2. One can use this to look at individuals or organisations or even technology.
3. Typically indicated when the research question starts with 'what'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. Be clear as to how the data will be collected – by documentary study and interviews are common.
7. Histories are naturally chronological and are characterised by epiphanies (pivotal events) and almost always exists in a context.

7.12 Rationale: Grounded Theory

Here the main idea is to use research to arrive at a theory based (grounded) on collected data. Grounded theory is quite difficult to understand and practice.

1. Grounded theory is used in situation where the theory is unclear or even unknown and so there is a need to **explore** seeking **description** and **explanations** in a domain.
2. One can use this to look at organisations or technology.
3. Typically indicated when the research question starts with 'why'.
4. You cannot control the events being looked at but the events need not be contemporary.
5. This is typically a qualitative study.
6. Be clear as to how the data will be collected – by documentary study, interviews, questionnaires etc.
7. Grounded theory is systematic in that the idea is to gradually move closer to a position where we can suggest a theory or proposition.
8. The basic unit of research is the category which is something that may represent a unit of information and might be almost anything.
9. The essence of grounded theory is in its data processing where various forms of coding are used to gradually unlock meaning in the data.

Open Coding – essentially the formation of the initial categories of information – it is characterised by looking for properties or asking when the something is a dimension of the research space.

Axial Coding – this is about trying to assemble that data after open coding. This can be done by using a diagram or some logic that connects things or looking for causes or looking for contexts and consequences.

Selective Coding – here the researchers invents a plausible storyline that integrates the categories in the axial coding model.

Matrix – a final step (though often omitted) is to produce a conditional matrix that is supposed to make clear the social, historical, technological or economic conditions that prevail in a situation.

Theory – one hopes that as a result of all this processing a theory will emerge which of course may go on to be tested by a formal experiment.

7.13 Rationale: Ethnography

This form of research is used when to immerse ourselves in the day to day life of an organisation or group. In this context ethnography is a description and interpretation of a cultural or social group.

1. Ethnography is commonly used when we want a reflective **description** expressed in an **interpretive** manner.
2. One can use this to look at individuals but more typically organisations.
3. Typically indicated when the research question starts with 'why'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. You may alter the events being looked at because you are normally a participant observer.
7. Be clear as to how the data will be collected – by participant observation.
8. Ethnography is about immersion in a culture: behaviours, language, structures and functions.
9. In such studies one often encounters gatekeepers, key informants and communication relies on a sense of reciprocity by investigator and his subjects.

7.14 Rationale: Requirements Gathering

Requirements are simply a statement of a systems service (what it must do) or constraints (what it does not necessarily do). In practice saying what a system must do is often extended to how it will do it. This method is a form of action research but it differs in that the only contact one has with the people involved is at the requirements stage and possibly at the implementation stage though this may vary depending on the systems life cycle employed. You should use this method when you are setting out to build an application of some kind such as a computer application. There are 4 stages of requirements.

Functional Requirements - These are requirements that say what a system does or is expected to do. Typically this would involve or include most of the following: process descriptions, details of all inputs/outputs and details of all the data that must be held in the system.

Performance Requirements - This is usually understood to mean requirements that describe aspects of the system that are concerned with how well it provides the main functional requirements. For example: performance criteria such as response times or how long it takes to print a report, data throughput and storage needs and security considerations.

Technical Requirements - This aspect of requirement looks at the tools and method used to build the system. For example, it may happen that you have to use a certain database package or for other reasons you need to select a particular scripting language and so on. More often than not this aspect amounts to looking at technical constraints that must be applied in building the system.

Usability Requirements - Requirements that ensure that there is a good match between the system and its users. In most cases usability is expressed in terms of measurable objectives.

7.14.1 The Requirements Document

The system and software requirements are usually documented in a formal manner so that ones understanding may be communicated to customers and system builders. The requirement document describes the following:

Services and Function – that the final system must deliver.

Operational Constraints - under which the system must operate.

Development Constraints - on the process used to develop the system.

Properties of the system - in the sense that it may have unplanned additional functionality.

Links - definition of other systems with which the system must integrate.

Domain - Information about the application - for example how to carry out certain tasks.

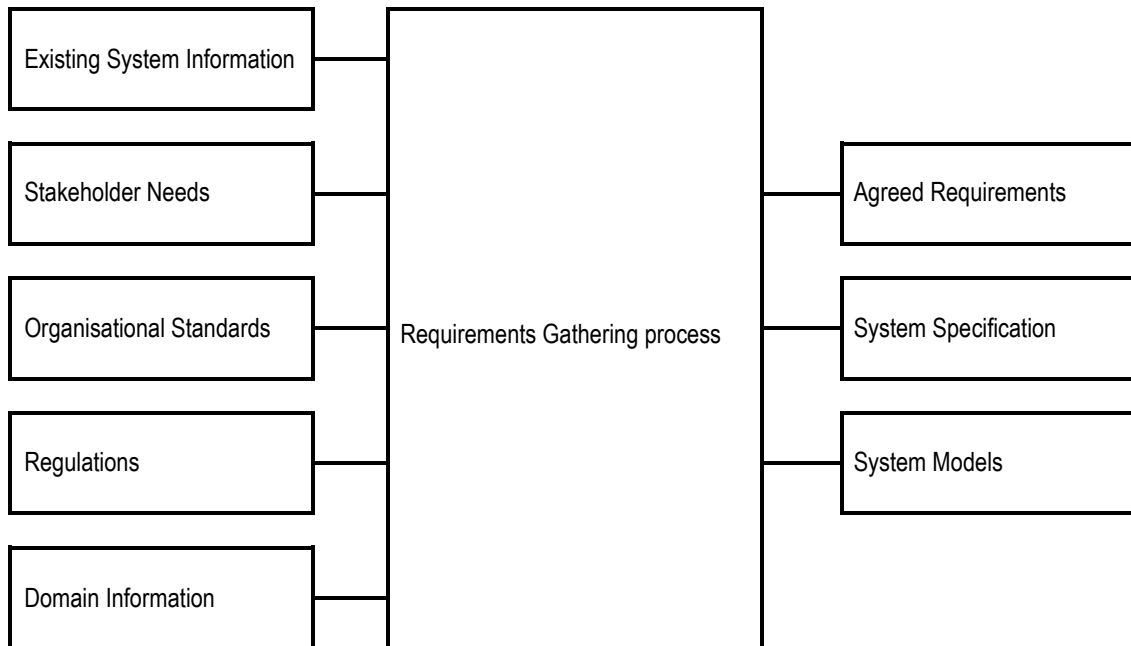

Definitions – acronyms, abbreviations etc.

7.14.2 Stakeholders

These are people who will be affected by the system and therefore should have a direct or indirect influence on the system requirements.

7.14.3 A Process Model

As a process model we might define the requirement process as follows.

7.14.4 Requirement General Questions

There are perhaps four general questions we might ask when attempting to gather requirements

Problem - What are the problems with the current processes?

Improvements - What are the improvement goals?

Reference. Kotonya, G. and Sommerville, I, (1997), Requirement Engineering, Wiley, ISBN 0-471-97208-8. This book is useful because it also contains excellent reading and reference lists.

7.15 Research Design

Finally, you must set out your research design. That is, explain how you will get your data – and this must be done in great detail. In summary, then, your research design is the blueprint of your research project which enables you to deal, systematically, with:

What questions to study?

What data is relevant?

What data to collect – you will need to work very hard here so that you can rely on your data.

Are there any practical limitations to what you can do

How to analyse the results – don't shirk this.

How to decide in which contexts your findings are applicable or can be exploited.

The main purpose of your research design is to help you avoid a situation in which the evidence you eventually collect does not address your initial question.

7.16 Research Process Development

It is quite common is many kinds of research but notably in Case Study and Action Research for the researcher's perceptions to change as data emerges. Often this will imply that the research design has to be changed or amended if it is to remain meaningful. These changes may be small such as a slight modification to the Research Question or aim but occasionally it may be necessary to make significant changes. For this reason researchers must always be careful in their design to allow a little flexibility if they can to accommodate possible unforeseen circumstances.

8. WORKBOOK 8 - BIBLIOGRAPHIC REFERENCING HARVARD APA

This workbook is a short summary of the APA style guidelines as contained in The Publication Manual of the American Psychological Association, 5e, 2001 (Subject Reference Collection: 808.02 AME).

The APA style is based on the Harvard referencing system whereby the date of publication follows the author name(s), and in-text references refer to items in the reference list using the author surname and date of publication, in brackets.

Referencing is important in all academic work as it indicates to the reader the sources of your quotations and borrowed ideas. Failure to indicate your sources is tantamount to plagiarism (literary theft). The purpose of the referencing system is to describe your sources in an accurate and consistent manner and to indicate within the text of your paper where particular sources were used.

Please note that there are two sections to this document:

How to **reference** correctly a source in the **bibliographic** section of your work

How to **cite** correctly a source in the **written** part of your work

Don't Get Caught Out! If you do not reference correctly you may lose marks or your work may be returned unmarked to you for correction. Therefore:

Keep a careful note of all sources used as you prepare your assignments.

Record all the details you need about a library book (including page numbers for any quotations) **before** you return it - someone else may have the book if you try to go back and check later.

Make sure you write down the source details you need on any photocopies or downloads you make.

Remember to print or save details of any website you want to refer to and record the date when you accessed the information.

8.1 Reference list (Bibliography) at end of Project/Dissertation

The reference list should be arranged alphabetically by author surname. The APA format requires book and journal titles etc. to be italicised, although we are not strict about that.

As a rule in projects and dissertations it is normal to produce two lists. The first is a reference list and that **MUST** only include sources you have cited. The second is a bibliographic list which includes all other sources you might have found but did not cite – this list is to allow the reader to explore the topic further if they wish.

8.2 Books

The details needed for a book can normally be found on the front and back of the title page. Make sure you locate the name of the publisher rather than the printer or typesetter. You need the name of the publisher in your reference list. Ignore any reprint dates; you need the date when the first, second, third edition etc. of the book was published according to which edition of the book you are using.

8.3 Journal articles

The details needed for a journal article can usually be found on the contents list, front cover or article itself.

8.4 Printed publications: Examples of References

The following are sample if how to correctly reference a source.

Book – pattern: Author, Initials. (year). Title of book. Place of publication: Publisher.

American Psychological Association. (1994). Publication manual of the American Psychological Association 4e. Washington, D.C.: Author.

Encyclopedia of psychology. (1976). London: Routledge.

Gardner, H. (1973). The arts and human development. New York: Wiley.

Moore, M. H., Estrich, S., McGillis, D., & Spelman, W. (1984). Dangerous offenders: the elusive target of justice. Cambridge: Harvard University Press.

Strunk, W., & White, E. B. (1979). *The elements of style* (3rd ed.). New York: Macmillan.

Note: Only list up to 6 authors. The 7th and subsequent authors are abbreviated to et al.

Edited book

Maher, B. A. (Ed.). (1964-1972). *Progress in experimental personality research* (6 vols.). New York: Academic Press

Article in edited book (Chapter) - The basic pattern for a reference to a chapter in an edited book (where the chapters have been written by several different people) is:

Author of chapter, Initials. (year). Title of chapter. In Initials. Name of Editor/s (Ed.) *Title of book* (pp.start and end page numbers of chapter). Place of publication: Publisher.

Vygotsky, L. S. (1991). Genesis of the higher mental functions. In P. Light, S. Sheldon, & M. Woodhead (Eds.), *Learning to think* (pp. 32-41). London: Routledge.

Encyclopedia entry - If the entry has no author, begin the reference with the entry title followed by the date of publication.

Lijphart, A. (1995). Electoral systems. In *The encyclopaedia of democracy* (Vol. 2, pp. 412-422). London: Routledge.

Government publication

Great Britain. Command Papers. (1991). *Health of the nation* (Cm 1523). London: HMSO.
Great Britain. Home Office. (1994). *Prisons policy for England and Wales*. London: HMSO.

Report

Birney, A. J., & Hall, M. M. (1981). *Early identification of children with written language difficulties* (Report No. 81-502). Washington DC: National Educational Association.

Conference paper in published proceedings

Borgman, C. L., Bower, J., & Krieger, D. (1989). From hands-on science to hands-on information retrieval. In J. Katzer, & G. B. Newby (Eds.), *Proceedings of the 52nd ASIS annual meeting: Vol. 26. Managing information and technology* (pp. 96-100). Medford, NJ: Learned Information.

Journal article - The basic pattern for a reference to a journal article is:

Author, Initials. (year) Title of article. *Title of journal*, Volume number - if there is one (Issue number), start and end page numbers of article.

Noguchi, T., Kitawaki, J., Tamura, T., Kim, T., Kanno, H., Yamamoto, T., et al. H. (1993). Relationship between aromatase activity and steroid receptor levels in ovarian tumors from postmenopausal women. *Journal of Steroid Biochemistry and Molecular Biology*, 44(4-6), 657-660.

Popper, S. E., & McCloskey, K. (1993). Individual differences and subgroups within populations: the shopping bag approach. *Aviation Space and Environmental Medicine*, 64(1), 74-77.

Weekly magazine article

Barrett, L. (2001, August 23). Daewoo's drive to survive in the UK. *Marketing Week*, 22-23.

Newspaper article

Caffeine linked to mental illness. (1991, July 13). *New York Times*, pp. B13, B15.
Young, H. (1996, July 25). Battle of snakes and ladders. *The Guardian*, p. 15.

Two or more works by the same author(s) with the same publication date - Where an author (or particular group of authors) has more than one work in a particular year, list them in title order and follow the date with a lower case letter a, b, c, ... For example:

Harding, S. (1986a). The instability of the analytical categories of feminist theory. *Signs*, 11(4), 645-64.
Harding, S. (1986b). *The science question in feminism*. Ithaca: Cornell University Press.

Anonymous works - If a work is signed "Anonymous", your reference must begin with the word Anonymous, followed by date etc. as normal. If no author is shown, put the title in the normal author position.

Note on source page numbers - Use pp. for page range only for encyclopedia entries, multi-page newspaper articles and chapters or articles in edited books. For articles in journals or magazines use the numbers alone.

Interviews and email messages - Because interviews and email messages are not considered recoverable data, you do not give details in your reference list. You should, however, cite an interview or email message within the body of your text as a personal communication: ...and this point was conceded (J. Bloggs, personal communication, August 22, 2001)

Legal References - Because the situation regarding legal references is complex and only US law is covered in the APA Manual, legal references will be covered in a separate guide.

Audiovisual sources: examples of references - Such sources are often complex but please note.

Films - The basic pattern for a reference to a film is:

Name of primary contributor - the director or producer, or both, Initials. (Role of primary contributor). (year). *Title of film* [Motion picture]. Country of origin - where the film was primarily made and released: Name of studio.

Reed, C. (Director). (1949). *The Third Man* [Motion picture]. United Kingdom: British Lion/London Films.

Spielberg, S. (Director). (1993). *Jurassic Park* [Motion picture]. United States: Universal Pictures/Amblin Entertainment.

If the film doesn't appear on the Library Catalogue, the Internet Movie Database <http://uk.imdb.com/> is a good place to check all the details needed for a film reference (follow the Company credits link to find details about the film studio/s involved). Alternatively, check Halliwell's Film and Video Guide.

Review of a film - If the review is untitled, put everything in square brackets in the normal title position and keep the square brackets.

Kinder, M. (2002). Moulin Rouge [Review of the motion picture *Moulin Rouge*]. *Film Quarterly*, 55(3), 52-59.

Malausa, V. (2001). Beauté du mensonge [Review of the motion picture *The Tailor of Panama*]. *Cahiers du Cinéma*, 558, 82-83.

Television programmes

Collinson-Jones, C. (Producer), & Dobson, E. (Director). (2003, July 14). Casualties of peace [Television broadcast]. London: Channel 4.

Single episode from a television series

This example shows the most complete information possible for a television episode. If details of the writer are unavailable, begin your reference with the name of the director.

Fraser, R. (Writer), & Geoghegan, S. (Director). (2003). Eyes wide open [Television series episode]. In P. Goodman (Producer), *Holby City*. London: BBC1.

Radio programmes

Portenier, G. (Producer). (2003, July 17). *Crossing continents*. London: BBC Radio 4.

Electronic sources: examples of references - The details shown below have been compiled according to the guidelines available on the APA Website (<http://www.apastyle.org>) in August/September 2001 (re-checked July 2003). Check this Website and the 5th edition of *The Publication Manual of the American Psychological Association* which is available in the Frewen Library for further guidance.

The basic pattern for a reference to an electronic source is:

Author, Initials. (year). *Title*. Retrieved month, day, year, from Internet address.
Banks, I. (n.d.). *The NHS Direct healthcare guide*. Retrieved August 29, 2001, from <http://www.healthcareguide.nhsdirect.nhs.uk/>

If no date is shown on the document, use n.d.

If the author is not given, begin your reference with the title of the document.

If a document is part of a large site such as that for a university or government department, give the name of the parent organisation and the relevant department before the Web address:

Alexander, J., & Tate, M. A. (2001). *Evaluating web resources*. Retrieved August 21, 2001, from Widener University, Wolfgram Memorial Library Web site: <http://www2.widener.edu/Wolfgram-Memorial-Library/webevaluation/webeval.htm>

Deciding your future. (2000). Retrieved September 5, 2001, from University of Portsmouth, Careers Service Web site: <http://www.port.ac.uk/departments/careers/plancareer/deciding-your-future.htm>

Electronic journal articles which are duplicates of the printed version - Use the same reference format as for a printed journal article but add "Electronic version" in square brackets after the article title:

Lussier, R. N., & Pfeifer, S. (2001). A crossnational prediction model for business success [Electronic version]. *Journal of Common Market Studies*, 39(3), 228-239.

If you are referencing an online article where the format differs from the printed version or which includes additional data or commentaries, you should add the date you retrieved the document and the Web address (URL).

Articles in Internet-only journals

Korda, L. (2001, July). The making of a translator. *Translation Journal*, 5(3). Retrieved August 21, 2001 from <http://accurapid.com/journal/17prof.htm>

Use the complete publication date shown on the article.

Note that page numbers are not given.

Whenever possible, the URL you give should link directly to the article itself.

Break a URL that goes onto another line after a slash or before a full-stop. Do not insert a hyphen at the break.

Articles retrieved from a database - Use the format appropriate to the type of work retrieved and add a retrieval date, plus the name of the database:

McVeigh, T. (2000, July 9). How your gestures can do the talking. *The Observer*, p.7. Retrieved September 10, 2001, from The Guardian and The Observer on CD-ROM database.

8.5 Citing references in the Text

There are basically two forms. The first is when the author's name is naturally part of the sentence and the second when it is just a reference. References are made from the text of the paper to the full details of the work in the reference list in the following manner:

It is a contention of the paper, and this contention is supported by Williams (1995, p.45) who compared personality disorders ...

When an author, or group of authors, has more than one publication in the same year a lower case letter is added to the date. For example:

In two recent works Harding (1986a, p.80; 1986b, p.138) has suggested that ...

With two authors both names should be listed in each citation e.g. Duncan & Goddard, (2003, p.99)

With three to five authors name all authors the first time, then use et al. (and others). For example: the first time it would be Moore, Estrich, McGillis & Spelman (1984, p.33) and subsequent references to the same publication would use Moore et al.

For six or more authors, use et al. after the first author in all occurrences.

Note that when the in-text reference occurs naturally within the sentence "and" should be used before the final author.

When a source has no author, cite the first two or three words of the title followed by the year. For example:

... in the recent book (*Encyclopaedia of psychology*, 1991, p.62) ...

... in this article ("Individual differences," 1993, p.12) ...

Web pages where no author is given

However, if the author is designated as "Anonymous", cite the word Anonymous in your text e.g. (Anonymous, 1993, p.116).

When using quotations in your text

Try to observe the following methods.

Gardner (1973, p41) stated that, "The relative importance of the systems may nevertheless remain in approximately the same proportion"

Smith (1991, p84) found that "...there is no evidence that chimpanzees can produce a drawing and discern the object represented in it..."

Occasionally, very occasionally you may need to cite a work that you discovered in another work because you cannot find the source then observe the following examples:

Smith (1970, p.27) cites Brown (1967) as finding ...
Brown (1967), cited by Smith (1970, p.27), found ...
It was found (Brown, 1967, cited by Smith, 1970, p.27) that ...

If you need to use this form your tutors must approve it and you must show that you have made every effort to track down the primary source.

9. WORKBOOK 9 – WRITING UP A RESEARCH PROJECT

This workbook is in several sections covering everything from project supervision to grading.

9.1 Your and Your Supervisor

The student supervisor relationship is very important if a high quality project is to be achieved. As a rule the supervisor will be interested in the topic area and will want to be active in its development although you as a student must do the work. However, your supervisor will not be expert in everything but will usually have some knowledge of simple statistics and the four main research methods: experiments, action research, surveys, case studies and application development.

9.1.1 Student Expectations

The normal expectation is that students have of their supervisor are as follows:

- Only be available for consultation for a limited time.
- Only supervise what the student does and not do the work for them.
- Advise on research design, scheduling and literature surveys.
- Advise on theoretical, conceptual and methodological issues.
- Advise on development of research skills.
- Advise on data collection, processing and analysis.
- Advise on ethical issues if they are relevant.
- Read, evaluate and be constructively critical of student work if given sufficient time.
- Have a good knowledge of the general area you are working in.
- Be in contact with the student regularly.
- Arrange if necessary supervision chat sessions.

For project students on distance learning programmes it will be possible to have meetings in the WebCT chat room, using IM or Skype where a full and detailed interaction can take place. These must normally be agreed with your supervisor and must be planned not to clash with other classes. However, some tutors may allow student to contact them any time they are seen to be online.

9.1.2 Departmental Expectations

Supervisors take a formal role and certain attitudes and actions are expected. In general they will:

- Visit the discussion board and email regularly within WebCT (at least 3 times per week).
- Set a mail forwarding address to their personal accounts in WebCT email settings.
- Devote at least 6 hours to the supervision process spread over the project duration.
- Conduct one-to-one chats as required with project students.
- Conduct student/supervisor communication within WebCT or their personal email account.
- Respond to a student query within a certain time frame (normally no longer than 3 days).
- Be familiar with all the project guidance notes and workbooks.
- Be familiar with the project chapter profiles.
- Make sure students know if they are to be away for an extended period.
- Be aware that students may make contact through any one of several WebCT accounts.

The essence of online supervision adequacy is based on the quality of communication between supervisor and student with the intent that we want the learning experiences to be exciting, stimulating and self-rewarding. In practice this means that communication must be frequent, lucid, critical and yet encouraging.

Supervisors should be aware that if they set email forwarding in WebCT they will effectively get an automatic alert when there is mail for them. If the student has also set mail forwarding then supervisors will be able to reply immediately otherwise they will have to go into WebCT. However, there is no alerting mechanism if a student posts a question into discussion so supervisors must visit the site from time to time so as not to miss any messages.

9.1.3 Supervisor Work Reviews

Supervisors will read your written work. However, when they do this certain rules apply:

Finished work – you should supply your supervisor with written work as it is produced chapter by chapter but it must be finished work. In this context finished work means that the format and content are the very best you can produce and in accordance to the guidelines found in this workbook. The tutor's role is not to act as some kind of filter for rough work or polishing multiple drafts which you want to improve in effect making them do the work for you. If a tutor suspects that the section you have sent in is not in its final form they will return it to you without comment.

Action on Feedback – if you are given feedback on any part of your work then you are expected to study it with care and commitment. However, it is up to you how to respond or even ignore what you are told but in all cases the consequences that follow are entirely your own responsibility.

Responding to Feedback – in all cases you are expected to respond to feedback. This may take several forms: writing to your supervisor saying that you don't agree with him or perhaps offering further explanation or as in most cases making changes to the content or structure of your project document. When you make document changes in response to feedback they are to be shown **shaded** so your supervisor can easily see exactly what you have added or amended.

Questions to Tutor - your tutor will not answer any questions regarding whether your work is right, wrong, is it a pass, what mark will I get or is it good enough. The only thing you can expect in this area is that you tutor may advise you that the work is not ready for submission to the university. If this happens it will be entirely your own decision whether to submit or not but if you do not submit a fail will automatically be recorded and you should be aware that extensions will not normally be given.

Response from Tutor - in most cases your supervisor will only suggest that you do something or ask a question designed to point you in a new direction. Normally, the tutor will not supply you with any project content since that must be provided entirely by you. The reason is that the work is yours not the supervisors.

Preparation - Your supervisor will expect you to be familiar with all the notes and workbooks contents. You should therefore be careful that you don't waste supervision time asking questions to which you already have the answers.

9.1.4 Chat Session

Chat sessions for project students will usually be one-to-one and typically used when there are particularly awkward difficulties – chat will NOT be the norm during projects and your tutor will have no expectation that chat will be used.

9.2 Overview of Project Structure

Here are some general guidance notes – they are NOT suggested chapters but general content guidance on the project as a whole and have a sharp process focus.

9.2.1 Introduction summary

This is about the problem theme and its setting, target, client context, topic area, personal theory, Research Question or application functional description and intended project outcome, general research orientation followed by a well-defined aim and sound set of objectives. The introduction is to be precise but concise taking a discussion form that is explanatory and focused on giving readers a clear, coherent and comprehensive view of what the project is about.

9.2.2 Preparation for Research

This is your study of the topic area and research methods that you will need to know about. You will have to justify and explain the methods you intend to use; it is also your study of other people's work in the area that you wish to investigate - and a description of how you learned from their research.

Literature Review - What has been done before in this area - related to a particular problem theme and your Research Question? This is all about preparing one's mind with all the topic area and research knowledge you will need.

Research Review - research into how the project investigation could be done and supported. At this stage student will already have an outline plan based on their approved specification but now the whole design must be thoroughly reviewed before actual work begins.

Knowledge of Alternatives – build a simple decision base which allows one to consider which methods could be used and how could they be used for this project.

Choices Made - which methods are to be used and rationally consider why they are good enough for the purpose.

9.2.3 Core Research

Here you execute the refined research design translated into a practical plan to obtain the collection of primary data and process it using acceptable methods into the intended project outcome.

9.2.4 Evaluation and Conclusions

This is the stage that looks at how one finishes off a project by a process of evaluation and the drawing of conclusions. In particular, it is needful to look at how one evaluates what was done and how it was done – that is, one needs to consider the project product (or outcome) and the project practice. For our purposes evaluating will be taken to mean reflecting on product and practice.

Many students confuse evaluation and conclusions but for a full consideration of the research work one must look at all project specific evaluation of results and outcomes as well as practices and then perform the more difficult step of drawing generalised conclusion about both product and practice.

Evaluation of Project Product – the specific project outcome or product is normally evaluated against objectives, other existing products, using defined criteria or some form of expert evaluation. Additionally, one needs to be aware of any constraints that might have an impact on the applicability of the outcome. However, typically one asks about the outcome (product): has it any value, who will use it, what will they use it for, will it get you your target effects that sort of thing.

Evaluation of Project Practice - evaluation of specific project practice is more difficult than evaluation of project outcome (product) and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking 'how well did I do it', 'was it successful' and 'should I on reflection have done it another way', 'did I make any mistakes', 'were there any surprises', "have I discovered any principles" and indeed did you learn anything. Additionally, one needs to be aware of any constraints involved, including time management that might have impacted on the use of best possible practices.

Conclusions – here we are trying to go beyond the obvious project findings and so we need to consider thoughtfully implications and meaning that arise out of an attempt to generalise about the topic based on your findings/outcome - that is you might have set your project in the Caribbean but do any of the findings have wider implications, are there general lessons to be learned, have you uncovered a principle or is there any sign of a best practice here that kind of thing.

9.3 Writing up your Project

The following sections describe elements that occur in almost all projects and which are generally important in constructing scholarly work. Do not be tempted to ignore these instructions – anyone who departs from the spirit of them may have their work returned for correction prior to formal marking.

9.3.1 Main Project Body Page Layout

The following shows how each page of a project report should look, note that each chapter starts on a new page and that it is NOT necessary to actually say Chapter 1, Chapter 2 and so on as it is the heading that is important. Do not use numbering to greater than three levels but you may use indented (but not bulleted ones) entries within a section at any level.

1. QUALITY CONTROL IN PROGRAM DEVELOPMENT

In this chapter the nature of quality will be discussed and its relation to physical measurable properties that might characterise quality.

1.1 INTRODUCTION

This project discusses a possible strategy for devising a program development methodology that goes some way to guaranteeing the qualities of the program code of delivered system. In particular it will concentrate on just two aspects - that of developing generic designs and code and how such designs could be assessed for quality and function. The strategy is based on the simple premise as endorsed by leading authors in the field such as Wilson and Bowers that categories of problem can be identified and formalised. It is the contention of this report that such a process would more or less automatically:

Reduce - the complexity of the design process itself.

Ensure - the quality of the final product by:

Giving managers more control over the product development cycle.

Giving users more idea of the kind of system they are likely to get and much more say in what the shape of the product will finally be.

Releasing programmers from the drudgery of having to design the same piece of code over and over again, thus enabling them to concentrate their efforts on new

1.2. Multiplicity of Design Factors

Every programmer has had the difficult experience of having to read and understand programs written by someone other than himself or herself. The sort of problem encountered may be aptly expressed in the following lines.

Everything has been thought of before, but the problem is to think of it again. (Goethe)

Many other authors, notably Frewin (1989) have discussed the notion of 'quality model ratios' and in essence this idea means that software systems have an implied model which can be accessed for

1.2.1 Multi-Tier Systems

In modern client sever systems

1.2.2 Interface Facades

In this case we look closely at the Internetetc

9.3.2 Plagiarism Checking

A software tool will check all your sources automatically and if plagiarism is identified it will be dealt with very seriously since the reputation of the whole course and of the University is at stake. You must remember, that copying, paraphrasing, summarising and similar techniques where the material is extracted from a source must be properly acknowledged. A simple rule is that if you use more than 6 consecutive words from a source it must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

9.3.3 Writing Abstracts and Identifying Keywords

The function of an abstract is to summarise your project, its context and its conclusions in order to give the reader an overview of the main project theme so that they can make an informed decision on whether they want to read the entire report. A good basic structure might be defined as follows but it will usually be limited to around 300 words.

What was the project about?

What did you actually do?

What were the conclusions/outcomes?

It is normal to add keywords or phrases after the abstract to act as specific pointers to content. There are no particular rules about how to construct these words or indeed how many there should be but typically there are 5 or 6 and to be useful they must be chosen with care in the sense that they might in themselves be regarded as a sort of abstract of ones work.

9.3.4 Standard Appendices

Project reports MUST include at least the following appendices:

Project specification and project Plan – it may be brought up to date from that submitted at the start

A glossary if this is appropriate

A full reference list of work that you cited

A bibliography (may be combined with your citation list)

Each Appendix should be introduced by a title where the number (12 in this case) should follow on from the numbering within the body of the report: **12. Appendix A – Project Specification.**

9.3.5 Typical Project Organisation

Below is a suggested organisation for your complete project.

Briefing Pages

Heading pages (examples follow later in the section)

Plagiarism declaration

Abstract for Report including keywords

Acknowledgements

Dedications

Content list (automatically generated) for all headings, tables and figures/graphs etc

Introduction:

Brief topic area outline and background to problem
Presenting Problem definition
Real World Target relevant to the problem
Speculation of problem causes/symptoms and possible solution routes
Personal Theory on the best solution route leading to a named outcome and actor
Research Question/Application Description
Scope and scale of work
Aim and Objectives

Literature Research (see Workbook 5 for recommendation for various project styles)
Detailed consideration of elements that help you focus on your topic area

Research Design

Research Method and its selection rationale in dealing with the research question/application
Process to collect Primary Data
Process definition to get from Primary Data to get an outcome

Application Testing (Engineering project only)

Design of Tests
Test Results and conclusions to be drawn from testing.
Implementation plans

Results Discussion and Presentation (study projects only)

Discussion and presentation of primary data
Generation of intended project outcome

Evaluation (this is specific to what you did)

Detailed evaluation of what was actually done – your practice
Detailed evaluation of your project product/outcome including objectives not met
Met/Not met objectives

Conclusions (here one tries to generalise what was done)

Main generalisations based on a consideration of both product and practice
It is also possible to examine the following minor conclusion elements but if this is all you produce the mark allocated will be very low.

- Usefulness of literature sources
- Future work/development
- Relevant aspect of the course used during the project period
- Changes one would make if project were repeated
- What you have learned
- Value-added features

References and bibliography (see workbook 5)**Content of Appendices**

The following items must be in a set of Appendices. These may be bound separately if the composite document becomes too large (more than 100 pages).

- Code listings
- Project Specification and project schedule
- Inclusions (copies of relevant documents such as policies, invoice layouts, diagrams etc)
- Questionnaires.
- Summary interview transcripts
- Details test plans
- Requirement catalogues
- Glossary
- Other

9.3.6 Project Types Sample Outline Contents

Broadly speaking there are two kinds of project: engineering where you build an application of some kind and study based where one would investigate in depth some idea. Here are some sample contents lists that show chapter or section headings for the different project styles. However, if it is obvious that these samples have just been copied into your project with minor changes then your work will be rejected. See Workbook 9 section 9.3.5 for further general details.

Sample Study Style Report Contents	Sample Engineering Report Contents
Title: Internet Marketing – A Users View	Title: BrokerBase – Insurance Sellers Information System
Chapter 1. Introduction to Internet Marketing	Chapter 1. Introduction to System
Introduction and contextualisation IT marketing problem theme Problem Theme, Target and Outcome Discussion and Exploration of Research Question Project aim and objectives	Introduction and Situation Overview Situation based Presenting Problem Application background and context Application overview Project aim and objectives
Chapter 2. Literature Review	Chapter 2. Literature Review and Application Scenario
Introduction to Internet Marketing Marketing Planning eCommerce Technologies and Tools Costs and Benefit Estimation Consumer Orientation and Market led operations IT supported Marketing and selling techniques Product, Price, Place, Promotion and Customer expectation IT supported Experiential marketing Security protocols and languages Auditing and secure payment systems	Outline of Insurance Brokerage practice Background Review of the Application Scenario Outline of Application Build Process and Tools
Chapter 3. Research Design	Chapter 3. Requirements Specification
Research Method Selection and Rationale Primary data collection process Data specification Data locations and expectations Collection Protocol Processing of Primary Data Collection Outline Results Project Outcome	Outline of the requirements (requirement catalogue into appendix) Research Plan for requirement gathering: functional, performance, technical and usability Outline Requirements catalogue Analysis and Evaluation of requirements
Chapter 4. Evaluation (Project Specific)	Chapter 4. System or Application Design
Evaluation of Project Outcome Evaluation of Research Methods and Protocols used	Principles used for this design Overall system design Build Process Overview Database design Component design Interface design including website
Chapter 5. Conclusions (Project Generalisations)	Chapter 5. System Implementation and Testing
Generalisations on the research Outcome Reflections on what was learned etc	Testing strategy Testing plans (detailed plan placed in appendices) Test results (detailed report placed in appendices) Application Implementation plans
	Chapter 6. Evaluation
	Evaluation of the application Evaluation of practice (methods and tools used)
	Chapter 7. Conclusions
	Generalisations based on the Application Reflections on what was learned Future work Etc
Notes	
1. Whatever the project styles the appendix must include: the project specification, glossaries, references lists, bibliographies. The appendices may be attached to the main report or they may be placed in a separate document.	
2. Remember these are just samples and you may well have different numbers of chapters and different heading and sub-headings	
Table 4. Sample Project Content Outlines	

9.4 Report Writing

In your research generally you will often have to write reports and of course you will have your final project report to write. Reports are a special form of writing and therefore you need to note that reports are:

- Written for defined purpose and targeted at a specific audience.
- Written systematically to present your of findings and outcome.
- Focused on what you have done.
- Information structured and formatted to lead reader quickly to main themes, findings and outcome

9.4.1 Structural Elements

It is important to structure all your work in a way that enhances its usefulness and utility. The following is a list of all the major structural elements, though there is no need to use all of them in every document you produce. The best advice is to choose a structure and then those elements that best suit the work in hand.

Structure	Description	Location
Title	A focused and short description of the document that summarises the deliverable element	Front page and above the contents list
Contents List	A short index based on the major chapters and/or sections	Before the main document begins but after the title page
Glossary	Used to list and describe special terms or abbreviations	Towards the end of the main document
Index	A detailed listing of all important words or phrases specifying location in main text	After the glossary if it exists otherwise after the main document
Appendix	For inclusion of explanatory notes, special documents or copies of originals	After the glossary but before the index
Footnotes	Notes at the bottom of pages and linked to pieces of text.	Immediately before the page footers
Headers	Standard text	Every page
Footers	Standard text	Every page
Keywords	Words or phases used to form a simple classification of your work	Near front of report
References	List of all reference material in an approved manner	Toward end of document
Table 5. Main Document Physical Structural Entities		

Organisation	Description
Chapters	Major elements in the development of the subject matter of the document
Sections	Minor elements in development of each chapter
Headings	Major Information Content indicators
Indents	Used to emphasise small but important points in the text
Bullets	Used to further emphasise an indented text
Tables	Used to represent important information concisely
Paragraph numbers	Used when it is necessary to reference all parts of a text
Page numbers	Used for indexing purposes
Diagrams	Used to show idea or data pictorially
Captions/Legends	Added to diagrams where necessary
Columns	Use when the subject material lends itself to such a view
Table 6. Main Document Structural Devices	

Presentation	Description	Examples
Font	Letter style and size	May be proportional or fixed point
Renditions	Printed form of font	Bold, underline, italic, reversed
Orientation	Page format	Portrait or landscape
Form	Delivery form	Paper, electronic
Table 7. Main Document Structural Properties		

9.4.2 Report Writing Stages

There are a number of stages to writing a report and they require you to be focused on what you are trying to say at the core of your report.

What are your trying to show – this really goes along with the underlying purpose of your research question – typically this will be about wanting: to inform, to explain, to evaluate, to prove, to advise, to recommend, to predict or to bring about changes.

Collect and sift material – it is important to jot down ideas relevant to your purpose. These jottings will help you form an action plan for gathering information from other documents, visits, interviews, observation, surveys etc.

Note – the exact location of information sources as you find them using Harvard APA format

Organise and structure the material - group your work into chapters, sections, sub sections, tables, appendices and so on and ensure their presentation order is logical.

Draft and edit/redraft – to get a good report you may well have to re-write it several times and this may include complete re-ordering. It is important that you need to be concise and use a formal language but it must be clear and concise. Use simple, straightforward words and sentence construction and make sure your spelling and grammar are faultless. Use clear headings and sub headings with bulleted indentations.

Thematic – make sure your work has clear themes that are easy to follow.

Plain English - do not try to be over-clever or fall into jargon.

Read Saunders chapter 13 pages 414 to 443. Don't skim on this or I might skim when I mark inferior work!

9.5 Project Submission Regulations

Successful project reports may be lodged in the University library, it is therefore important that reports follow a standard binding format as described below. Project reports that deviate from these regulations may be penalised and returned to you for correction and in extreme cases, failed.

Submission - two full bound A4 portrait orientation copies of your report must be submitted by the due dates. The report may NOT be submitted electronically – the copies must be sent by courier to reach us by the defined dates. However, you must also submit soft copies on either floppy disc or CD/DVD.

Presentation and Submission Checklist – your project report must be submitted using the correct form shown in Workbook 10. The form must be bound into your project.

Report Length - the maximum permitted report length is 15,000 words, which usually translates into around 50 to 100 pages (excluding appendices). If your report is likely to be significantly longer than this, consult your supervisor as to what to include and what to exclude. You are warned that should you exceed the permitted maximum length the University may return your work unmarked.

Binding - the project and any separate appendices should be securely bound using tape or book binding - if that is not available then plastic ring binding may be used. No other form of binding is permitted. Binding covers should be a card of weight of 140 gsm and the normal colour is to be RED but any other colour may be used in case of sourcing difficulties

Front Covers Format - the front cover appropriately spaced vertically should conform to the pattern shown below using 24-point Arial Narrow with centred text and bold as shown. Do not include the square brackets when you complete these formats as they are just placeholders

University of Portsmouth

School of Computing

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[Student No.]

Supervisor: [Name of supervisor]

Project unit Code [Project unit code]
[Month and Year, e.g. September 2004]

Title Page - the first project contents page, appropriately space vertically must contain the following information in the order shown below using 12 point Arial Narrow/Time Roman type throughout. Do not include the square brackets when you complete these formats as they are just placeholders.

University of Portsmouth

School of Computing

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[Student No.]

Supervisor: [*Name of supervisor*]

Project unit: [*Project unit code*]
[Month and Year, e.g. September 2001]

Abstract - [The abstract of the project should be between 150 and 300 words in length and constructed to say what the project was about, what you did and what were the conclusions]

Keyword List - [List of appropriate key words]

Acknowledgements Page - it is common practice to add a page listing those you wish to thank for their help. Acknowledgements should **only** be given to people who helped you directly with your work but were not involved in it. For example, if a colleague supplied you with a statistical analysis they should be acknowledged. However, it is not usual, necessary or desirable to acknowledge your parents, your wife or your friends.

Submission Form and Plagiarism Declaration

You must add the following two pages which require a signature. In practice one adds the signature to the final bound copies.

Declaration of presentation Standards

Include at this point a completed copy of the project submission checklist shown in workbook 10. Be warned, that if you tick this page and the relevant element is not found to be present, the work will be returned to you unmarked for correction.

Plagiarism Declaration

I confirm that the enclosed written work (including application code) is entirely my own except where explicitly stated otherwise. I declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions. I understand that wherever 6 or more consecutive words are extracted from a source they must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

Include as appropriate

9.6 General Grade Criteria

Workbook 14 gives general guidance as to how projects will be assessed and also contains a table of the criteria used, although the emphasis given to various aspects may vary depending upon the nature of the work and should be explained to students in assessment specific criteria.

9.7 Project Examination Board Reflections

This is a discussion based on observations made on the marking forms and in the Examination Board regarding the quality of the submitted document as final Master's projects/dissertations. Most of these faults are due to shallow and sometimes very shallow thinking on the part of the project student and that is unacceptable at Master's level. The following points are to help both supervisors and students avoid known pitfalls and so produce a project document to a high standard.

9.7.1 Project Introduction – Study Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem definition – common deficiencies were no discussion or poor discussion of what problem was being addressed by the project. Without such a discussion it is almost impossible for a reader to get any grasp of what the project is about. In projects we want to see just ONE major problem theme not several so it often requires clear thinking to set it at the right level. (See workbook 6 section 6.2 and 6.11)

Target, Outcome and Actor – there is often considerable confusion over these ideas. The target is about what might happen in the real world based on the project outcome but often students cannot distinguish what the project will generate and what might be done with that project outcome by situation actors. As a simple example, students might say that the project outcome is "improved accuracy in data entry" when what they mean one supposes is that in their project they will design (say) a new training programme that will be used to get the real world target of improved accuracy. (See workbook 6 section 6.3, 6.4 and 6.5)

Speculation and Personal Theory – students are encouraged to speculate about problem causes and solution routes to arrive at a personal theory about the problem theme and how it might be resolved leading to a suggestion of an expected project outcome. A reader expects to see some indication as to what form the project outcome will take and in addition some discussion of the form to at least show that it is likely to go some way to resolving the stated problem theme and can indeed be used by the named situation actors. Unfortunately, the outcome was often missing or confused with the target and even when the Research Design was consulted a typical reader could still not see what the project outcome was supposed to be. Here we want to see ONE major form outcome for each project. (See workbook 6 section 6.6).

Research Question – often missing, badly worded, many of the 6 required features missing or multiple questions offered (sometimes all in one sentence). One common mistake was to ask a question in the form (or some equivalent) of "is it possible...." - the point is that in such questions the answer is almost always that it is possible so the research effort becomes pointless. (See workbook 6 section 6.8)

9.7.2 Project Introduction – Engineering Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem Theme - there was either no discussion or poor discussion of what problem theme the application being built was supposed to resolve. When this happens it is almost impossible for a reader to get any grasp of what the project is really about. (See workbook 6 section 6.2 and 6.11)

Functional Description - many students could not provide a short functional description of the application they were going to build. The most common thing for students to do instead was to provide an overview of the application architecture. This is hopeless as architecturally almost all Engineering projects are the same in that they typically have a database and a webpage for example. This implies that students cannot or do not want to make a distinction between how an application is built and what its purpose is.

9.7.3 Aim and Objectives

In many case these elements were missing altogether. In other cases one could barely link the aim to the Research Question or application description. However, of most concern was an apparent inability in many students to write a coherent and reasonable set of objectives. Not to be able to write an aim and more particularly objective is representative of a gross student weakness and it should never occur in Master's level work.

Aim - usually composed in a reasonable way but there does seem to be an inclination in some students to cram everything into the aim as if they are some kind of superman. The recommendation is to have just ONE clear activity mentioned in the aim and that should be accompanied by a just one clear outcome for the aim. (See workbook 6 section 6.13, 6.13.1)

Number of Objectives - often there were far too many to be in any way practical for one student in the time available and often this was because they were all expressed at different levels of project resolution or confused with minor project tasks. (See workbook 6 section 6.13 and 6.13.2)

No Visible Outcome - there were many, many cases where the objectives had no visible outcome. Far too often we got phrases such as: "To understand...." or "To analyse...." without any object to the sentence so there was no outcome that was visible. Without a named outcome there is no way that the objectives can be seen to have been completed. (See workbook 6 section 6.13 and 6.13.2)

Not Project Bounded - there were many students who cited operational objectives as outcomes. For example it was common to see lines such as "To improve the workflow in the invoicing section". Here is a case where such an outcome cannot be written into a document or be in practical terms viewed and so cannot be used in a project. Typically, unbounded objectives refer to something that might happen based on the project outcome after the actual project has been completed (See workbook 6 section 6.13 and 6.13.2)

Objectives as Requirements - very commonly but still rather worryingly, many students, on Engineering projects, seem to think that objectives are the same as application requirements. (See workbook 6 section 6.13 and 6.13.2)

Objectives as Benefits - less commonly but still rather worryingly, many students, on Engineering and study projects, seem to think that objectives are the same as benefits. For example, in a study project on CRM systems what one often finds in place of project objectives is a list of benefits of implementing CRM. Similarly, for Engineering projects we see objectives written as a set of benefits of using the application being used later on in the real world. (See workbook 6 section 6.13 and 6.13.2)

9.7.4 Literature Review

In research the literature review is regarded as being essentially preparation of the mind. It follows, that to be serious about this step one has to be evaluatory and reflective as you read and write. Ideally one needs a strong theme which is used to weave an expository and exploratory discourse that unites and builds one's understanding and ideas with what has been written by other authors on one's core topic area.

For projects a full literature review is only needed in the case of a study project. For Engineering all that is required is a thorough overview of the application area. So for example, if an application where about Insurance brokerage then all that is required is a description of what brokerage is but only to the level necessary to understand the requirements. See workbook 5 but section 5.2, 5.6, 5.7 and 5.8 should be studied with care.

Structure - many reviews were poorly structured and one often felt that the students had just written down the material as it occurred to them without any thought as to a wider readership.

Theme - often there was no detectable theme connecting the various sections of the narrative and a reader would therefore be forced to guess at how all the various elements were connected.

Value Added - the most common flaw was to see a review that was entirely or almost entirely made up of quotations, paraphrases or summaries so that the 'hand' of the student was not detectable anywhere in the work. Such work is not evaluatory and gives no indication whatever that the student has learned anything of value or indeed anything at all. It is often the case that one feels the student has no notion of the literature being a driver that may mean they have to accept new knowledge, gain further experience, modify existing knowledge or even abandon what they thought was sacrosanct and sadly no belief that their own views and experiences are also important.

Citation Style - two things are evident here. Firstly, one finds that too often citations are limited to the Literature Review. Secondly, the actual style used is very poor and commonly we see the form (Burk, 1992 p45) placed at the end of a sentence or paragraph - this is not acceptable and can only mean the whole paragraph has been paraphrased. The ONLY correct use of this bracketed style is in a passing reference to a text. (See workbook 8)

Worthless Quotes/Paraphrases - it is unfortunately only too common to see an appeal to some text or other for information that tells you either common knowledge or makes an obvious observation and so the citation is worthless and is representative of weak scholarship and laziness where a student is just trying to add a citation because he knows that such things are desirable. For example, quoting an author who says that "Object Orientation is now routinely used in software construction" is representative of common knowledge or quoting an authors who "says change is inevitable" is something that one might regard as obvious.

9.7.5 Research Design

These were often far from satisfactory and often read like a joke delivered without the punch line. The students are taught that essentially there are two phases. The first phase is the process used to get primary data items that are formed into a set. Once the collection phase is completed we move on to the second phase of processing where the set of primary data items is processed to get an answer in the form of expected project outcome. Particular points are:

Research Phases - In many cases students were unable to distinguish the processing needed to get a set of primary data and processing of the set to get an outcome. It is quite common to see these two phases ignored or become completely muddled leading to a poor research outcome because the student loses his/her focus and often appear to have no clear idea what they are doing. The phases are:

Data Definition and Collection - a process or processes used to define and create a primary data set. It typically has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the data and present the data.

Data Processing - a process or processes used to manipulate the primary data set to get the project outcome.

No Outcome - often it seemed as if the student had no idea what project outcome to expect so when one looked at the processing there was no sense that the primary data was being used in any way to generate the required project outcome. See workbook 6 section 6.4

No Situation Actors – this occurs when we have an outcome but no idea who (person or persons) will use it to generate the target effects. See Workbook 6 section 6.5

Primary Data - many students seem to have only a vague notion of what primary data is and will often, very often, confuse or think that primary data is the same as the method of collection. This confusion is often evident with some students thinking that only questionnaire data could possibly be primary data.

Primary Data Definition - Primary Data is new data in the sense that it will not exist as a set until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data set is representative of some aspect of the area under investigation and can be processed to get a defined project outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

For example, one student took the definition and then read through an accounting system manual for his company and extracted all the functions and claimed that was primary data because he was going to use it to define what an accounts package should have by way of functionality but seemed unable to see that the manual had effectively done that already. (See workbook 6 section 6.7)

Research Method Justification - often students could not distinguish between Research Method and Data Collection Protocols. Research Methods are frameworks such as Case Study, Experiment, Action Research and so on. Collection protocols are based on: interview, questionnaire, observation, role playing, seminars, focus groups and so on. The sorts of justifications used are of the form "I have chosen case study because Saunders (2005, p92) said case studies are good..." - this is hopeless and implies no real thought. Justification must be built from a sound understanding of a particular Research Question, its expected form of answer (project outcome) and the Primary Data needs and at least an overview of which method is likely to be best in a given situation. (See Workbook 7)

Practicality - many plans were over-complicated with students trying to use multiple methods and then ending up with masses of data they had no idea what to do with. There is only limited time and so students should be encouraged to focus on just one Research Method although of course several collection protocols may be involved.

Data Collections - in many cases all an examiner was able to see were presented results but often one simply could not tell if any primary data set was involved and the results just seemed to appear 'out of the air'. The marking guide is quite specific and projects must be clear about both processed data and raw primary data sets. Without this we cannot feel confident that students have done any actual research. Typically, the primary data set is placed in an appendix and might be in the form of a summary table of questionnaires results or summarised transcripts. Correspondingly, the processed primary data set is expressed as charts, graphs, tables, reports and so on in the body of the project report.

Processing - this is one of the most disappointing elements. Processing is all about transforming your primary data set into the project outcome. Far too often all we see is the processing of individual primary data items with no attempt or very weak attempts to really supply an answer to the Research Question in the form that was specified.

Location - there were quite a few projects where it was more or less impossible to see where the primary data came from and often this was accompanied by a very ordinary set of results that could have been written by almost anybody with a superficial knowledge of the subject area.

9.7.6 Research Results Processing

There were some very good examples but often this section was very routine and very disappointing.

Repeating - it was very common to see a chart for example, displayed and then underneath the student simply repeated the data that was in the chart in words. Such a practice is worthless. What any data related narrative is supposed to do is to tell the reader what the data means and what implication it might have - that is we expect to see some analysis and evaluation of the data in terms of the Research Question.

Focus - the focus of processing the primary data is to create a kind of transformation that generates from the primary data set the expected project outcome - unfortunately, this aspect was often absent. Typically in a survey for instance we have page after page of charts analysing individual data items but no attempt to sum it all up and reach a conclusion based around the Research Question.

9.7.7 Evaluation and Conclusions

These sections in a lot of student work are indistinguishable. The reason there are two sections with marks attached is because:

Evaluation - here one focuses specifically on the project outcome and research methods - that is we evaluate our product (outcome) and the methods used in its generation. Notice here this is NOT about generating the outcome that would have been done in the primary data processing section

Conclusions - here the attempt is made to say what it all means - that is trying to generalize the findings. So for example, suppose the outcome is about the use of Agent technology in eCommerce web sites then in conclusions one might try to say what a particular project outcome means for any eCommerce site or in fact any website. In a similar kind of way, if a particular application had been built we might try to say whether it might be applicable in other situations or whether some features of the design can be transferred to all applications of that type.

9.7.8 Ignorance of Project Marking Criteria

Many students show an almost complete disregard for the way a project is marked and so often automatically lose marks. Students must therefore carefully study the marking forms so that they know what components are regarded as essential to any project and therefore carry marks. (See workbook 11 or 12 as appropriate)

10. WORKBOOK 10 – FORM: PROJECT SUBMISSION

This form **must** be completed and included in your project submission. If you are unable to tick every box then your work is not ready for submission.

Project Word Count	Exclude appendices. If maximum is exceeded marks may be lost or the project rejected
	The report length is within the stated guidelines (15,000 words maximum excluding appendices)
	I have included all making elements indicated in workbook 11 Or 12 as appropriate and noted the marking guidance notes
	I have studied the guidance notes on common project faults found in section 9.6
	I have prepared two bound copies of all my project work including any separate appendices
	I understand that I may use one or both sides of the paper when printing the report.
	I have included a full contents list, table list and diagram list all numbered consistently
	I have used good quality A4 paper, normally in portrait orientation with a weight between of 80 and 100gsm.
	I have made sure that the pages are in the right order and none are missing
	I have used MS word .doc format
	I have formatted the front cover and title page as required and added the necessary plagiarism declaration.
	All my text is single line spaced at 6 lines per inch/25.4 mm.
	All my main text, including headings is in 12-point font (Arial Narrow is recommended)
	All my text in tables and diagrams is 10-point font (Arial Narrow is recommended)
	All main text is right and left justified
	No headings at whatever level are indented
	Headings are NOT followed by a blank line
	Headings are in the same font and size as the main text but are shown in bold type
	No numbered headings are orphaned (that is all heading must be followed by some text not immediately by another heading)
	I have used a single blank line to separate paragraphs
	All chapters and appendices are numbered sequentially (1, 2, 3,...)
	All subsections are numbered (2.1, 2.2,...) and none of my sections numbers exceed three levels (1.2.1, 1.2.3 ...)
	All my margins: (top, bottom, left and right) are 20mm
	All pages have footers in 10-pt Arial Narrow in form: Page 12 of 97 - J.Letto Student No. 567543 Submission Date: 12.10.07
	I have cited other people's work properly using the Harvard APA format
	I have included all citations in my list of references
	My abstract accurately summarises all of the report, not just parts of it
	All my chapters and appendices start on a new page
	I have included appendices, where appropriate, covering: project specification, Project Plan, Requirements document(s), design document, screen shots, source code, user documentation, test results, evaluation results, questionnaires, etc.
	My supervisor has read each chapter as the work progressed.
	My supervisor has read the whole report
	I understand that indented sentences can be used where appropriate but bullets are not recommended (see 9.3.1)
	I understand that page headers are not required
	I understand that each of my chapters should start with an introductory section that explains what the chapter is about
	I understand that each of my chapters should end with a summary and a helpful link to the next chapter
	I have fixed a copy in .doc format of the project document and any appendices on floppy/CD/DVD to my project submission
	All my primary data (including requirements data) is original to this study and collected by me for this specific project purpose
	My primary data collection is available in the project document or appendix (if necessary in edited or summarised form)
	Engineering Projects only - I have included an executable file of my application on an attached floppy/CD/DVD
	Engineering Projects only - Application Operating instruction are on the attached floppy/CD/DVD as well as in the appendix
	Engineering Projects only – In my application I have not used illegal copies of any software or included any software where there is an expiry date which may render the application inoperable in the future.
	Engineering Projects only - I understand that the copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If, and only if, this is not possible then I have included in my project a supervisor signed set of screen shots in the appendix confirming that he/she has viewed the application in action.
Signature of Student. _____ Date. _____	

11. WORKBOOK 11 – FORM: STUDY PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

STUDY STYLE		Postgraduate Project Marking Form						STUDY STYLE	
Name of Student							HEMIS No.		
Brief Project Title							Total Mark	%	
Recommendation	If the mark awarded is a fail circle your opinion						Re-Work	New Topic	
Name: Supervisor									
Name: Marker									
Marker Status	Supervisor		Moderator		3 rd Marker		Re-Marker		
Project Unit	PJ.NCC								
Plagiarism	N	Y	Is PLAGIARISM or another unfair act is suspected						
External Examiner	N	Y	Refer to the External Examiner (if "Y" add comment in section G)						
Content	Y	N	Can you confirm that this project fulfils the criteria for the Unit						
References: See Workbook 11 for detailed marking guidelines and Workbook 14 for general expectation and grade criteria notes									
Section A - Marks for Planning and Preparation							Weight	Mark	
1.	Project specification, including project plan						5		
2.	Review of the topic area literature						15		
Sub-Total							20		
Section B - Marks for Project Introduction									
3.	Presenting problem and its exploration including the Research Question						5		
4.	Discussion of the project's scope, scale, aim and objectives						10		
Sub-Total							15		
Section C - Marks for Project Primary Data Research and Outcome Generation									
5.	Selection and justification of Research Method						5		
6.	Primary data collection plan including data specification						10		
7.	Primary data processing plan to get expected outcome						10		
8.	Presentation and discussion of the collection of Primary Data						10		
9.	Description and discussion of main project outcome						10		
Sub-Total							45		
Section D - Marks for Project Evaluation and Conclusions									
10.	Evaluation of the project outcome (Project Specific)						5		
11.	Evaluation of project practice (Project Specific)						5		
12.	Statement of conclusions and reflections (Project Generalisations)						10		
Sub-Total							20		
Section E – Qualitative Assessment matrix based on University Grade Criteria									
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words			
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless			
3.	Report structure	very poor	poor	satisfactory	good	excellent			
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report			
5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours			
6.	Project idea	trivial	easy	modest	challenging	Difficult			

7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Primary data collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Data processing	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
14.	Main project outcome	Worthless	obvious	useful	original	exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

--

Section G – Note here elements you want brought to the attention of the External Examiners

--

Signed		Dated	
---------------	--	--------------	--

Study Format Marking Form Guidance notes These notes must be read in conjunction with the grade criteria and associated notes found in Workbook 14.
Section A - Marks for Planning and Preparation
1. Project specification, including project plan
Reference: Workbook 3 section 3.3 for general notes and section 3.5.2 for an example specification
Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.
2. Review of the topic area literature
Reference: Workbook 5 section 5.2 and 5.6 in particular, Workbook 8 and Workbook 9 section 9.6.4
Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers and generally be focused on the central project topic. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.
Section B - Marks for Project Introduction
3. Presenting problem and its exploration including the Research Question
Reference: Workbook 3 section 3.3 and 3.5.1, Workbook 6 sections 6.2, 6.6 and 6.7 and Workbook 9 section 9.6.1
All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Research Question with a defined form of answer (project outcome). It is very common to see an expression of a problem as "my problem is to find a solution to..." or expressed in such a way that it is in effect a solution and such expressions are indicative of students who do not know what the problem is but nevertheless know what the solution is. Similarly, students who list multiple problems, have no Research Question (or a very poor one) and do not discuss the form of outcome expected are embarking upon projects where there is no clear focus and these typically fragment when it comes to the core research and one most often cannot find any clear project outcome later in the work. It is also useful at this stage if there is some indication of the Basic Activity for Generating Data (BAGeD) so that one can feel sure that the student is aware of what primary data they need in order to generate the intended outcome.
4. Discussion of the project's scope, scale, aim and objectives
Reference: Workbook 3 section 3.5.2 (example), Workbook 6 section 6.1 and Workbook 9 section 9.6.3.
Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition, expected form of outcome and Research Question all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.
Section C - Marks for Project Primary Data Research and Outcome Generation
5. Selection and justification of Research Method
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Markers should look for a rational and thoughtful choice of Research Method focused on resolving the stated problem theme. In practice this implies a consideration of primary data needs, location of primary data and the collection protocols that might be used. Markers should guard against rationales that amount to saying that some text book or other said method X or Y was good for certain kinds of scenario – that is copies of generalisations about Research Methods found in books do not amount to a rational for a specific research situation. Furthermore, markers need to feel confident that the student understands the distinction between a Research Method and the collection protocols used within them.
6. Primary data collection plan including data specification
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
This is a crucial stage in a research based project and markers must be confident that the plan is practical. A marker must look for a clear core activity represented by a statement about of BAGeD and that core activity should be surrounded by whatever other processes are needed to ensure reliable collection of the primary data. The whole primary data collection plan has four steps which must be visible in the project document: data definition, data location, data collection and how the whole collection of primary data is to be presented. Markers should also take care that the formation of a collection of primary data is not confused with the processing of it to get the stated project outcome.

7. Primary data processing plan and presentation of the expected outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for clear evidence that the student has taken the collection of primary data they obtained earlier in the project and now process that whole collection to get to a clear presentation of the project outcome. It is therefore important that markers can see what processes were applied to the collection of primary data to get the outcome – without this process visibility there is no evidence as to how the project outcome was actually obtained. Markers should be wary of processing plans that say such things as “I will look at the data” or “I will analyze the data” or “I will use SPSS” as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same data collection they could apply the same processes and get the same or at least a very similar outcome.
Markers should also be aware that very often students will often process individual data items – such as might be found on a questionnaire, but never get to a point where the stated project outcome is derived from the collection of data.
8. Presentation and discussion of the collection of Primary Data
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for visible signs of the collected primary data. The primary data collection is most often presented in tabular form in the appendix and might be displayed as graphs, charts, tables or diagrams in the main project document.
9. Expression and description of main project outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
The intended project outcome must be clearly visible – for example if the intended outcome is a model then that must be clearly shown in some acceptable form and be based on the processing plan outline in section 7. Markers must therefore take great care that the presentation of primary data and the processing of individual data items in the collection are not offered as a substitute for the student generating the intended project outcome.
Section D - Marks for Project Evaluation and Conclusions
10. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project outcome so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution (project outcome) or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project outcome. The section is not intended for vague thoughts about the topic but a considered evaluation of the project outcome when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
11. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate here. This section is important as this is where one expects to find some information on what the student has learned about the way they work and the tools they used. It is unfortunately often the case that students have very little idea about what they did apart from stating vague activities such as “look at”, “analyze” or “use SPSS” so without anything concrete to evaluate they resort to the routine and say “the survey process went very well” or “my case studies generated useful data” or else they simply ignore this form of evaluation altogether. Evaluation of project practice is difficult and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking ‘how did I do it’, ‘was it successful’ and ‘could I or should I on reflection have done it another way’. Additionally, one needs to be aware of any constraints involved, including time management and particular skills that might have impacted on the use of best possible practices.
12. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a project outcome was based on case studies and the outcome was a review of IT outsourcing in Hong Kong then here we might expect to see the student consider the outcome he obtained which refers to Hong Kong and then consider and discuss whether that outcome has wide applicability, for example, to China, South East Asia or even the world as part of a Global economy or is it just specific to that local situation. Essentially, one is asking what do the outcome ‘mean’ when set in a wider setting. It follows that the focus of awarding marks here is for project generalisations.
It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such as future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

12. WORKBOOK 12 – FORM: ENGINEERING PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

ENGINEERING STYLE		Postgraduate Project Marking Form				ENGINEERING STYLE	
Name of Student					HEMIS No.		
Brief Project Title					Total Mark	%	
Recommendation	If the mark awarded is a fail circle your opinion				Re-Work	New Topic	
Name: Supervisor							
Name: Marker							
Marker Status	Supervisor		Moderator		3 rd Marker		Re-Marker
Project Unit	PJ.PEA						
Plagiarism	N	Y	Is PLAGIARISM or another unfair act suspected				
External Examiner	N	Y	Refer project to the External Examiner (if "Y" complete section G)				
Content	Y	N	Can you confirm that this project fulfils the criteria for the Unit				
References: See Workbook 12 for detailed marking guidelines and Workbook 14 for general expectation and grade criteria notes							
Section A - Marks for Planning and Preparation					Weight	Mark	
1.	Project specification, including project plan				5		
2.	Review of the application/product area and its client/business setting				10		
Sub-Total					15		
Section B - Marks for Project Introduction							
3.	Presenting problem and outline proposal				5		
4.	Discussion of the project scope, scale, constraints, aim and objectives				10		
Sub-Total					15		
Section C - Marks for Project Primary Data Research and Outcome Generation							
5.	Detailed requirements collection plan based on proposal				5		
6.	Analysis of requirements: functional, performance, technical and usability				5		
7.	Presentation, analysis and discussion of the design				10		
8.	Discussion of build process and design implementation				10		
9.	Application testing process and results				5		
10.	Implementation plans				5		
11.	Attributes of the project artefact (e.g. quality, reliability, etc)				10		
Sub-Total					50		
Section D - Marks for Project Evaluation and Conclusions							
12.	Evaluation of project product against requirements (project Specific)				5		
13.	Evaluation of project practice (project specific)				5		
14.	Statement of conclusions and reflections (project generalisations)				10		
Sub-Total					20		
Section E – Qualitative Assessment matrix based on University Grade Criteria							
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words	
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless	
3.	Report structure	very poor	poor	satisfactory	good	Excellent	
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report	

5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours
6.	Project idea	trivial	easy	modest	challenging	difficult
7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Requirements Collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Design Expression	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
15.	Artefact Evaluation	worthless	obvious	useful	original	Exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Engineering Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.1 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the application/product area and its client/business setting

Reference: Workbook 5 section 5.2 and 5.6, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers. In Engineering projects the expectation is that the review will focus on the application area and be in enough detail to at least understand and gather the requirements. It is permitted to include technical material if they have a special or unusual significance to the application area but in so doing students must be aware that the routine inclusion of what at this level might be regarded as common knowledge in computing/IT will not attract any marks. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and Outline Proposal

Reference: Workbook 3 section 3.3 and 3.5.1 Workbook 6.2 and 6.5, Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Application Outline expressed as a functional description. It is very common to see an expression of a problem as "my problem is to find a solution to..." and this is indicative of students who do not know what the problem is but nevertheless know what the solution is. Students who list multiple problems, have no functional description (or a very poor one) are indicative of projects where there is no clear focus and these typically fragment when it comes to requirements gathering and often end in a very trivial application. Markers should be aware that students may avoid giving a functional description and instead offer a generic architectural one and this must be penalised as the student clearly does not know what function the application supplies

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.1 (example), Workbook 6 section 6.11, 6.9 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition and Application Outline all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Detailed requirements collection plan based on proposal

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful consideration of the Requirement Gathering process focused on obtaining sufficient information to build the intended application and resolve the stated problem theme. In practice this implies a consideration of application functions, location of requirements data and the collection protocols that might be used. Normally in research one would expect a rationale for the choice of Research Method but for Engineering projects it is taken for granted that the method is requirements gathering. Instead one should look for a clear focus on constructing a feasible and comprehensive requirements document based on the application outline. Furthermore, markers need to feel confident that the student understands the distinction between Requirement Gathering as a Research Method and the collection protocols used within it.

6. Analysis of requirements: functional, performance, technical and usability

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers must look for a clear Application Proposal and a requirements catalogue. Here one needs to see a discussion of the requirements to ensure they are credible (realistic), comprehensive, complete and stakeholders have been considered. One might also usefully consider the approach that was taken to gain them and whether they are of the form of strategic, tactical or operational.

7. Presentation, analysis and discussion of the design
Reference: Workbook 9 sections 9.6.5 and 9.6.6 and Workbook 7 section 7.9
Marks are awarded here for clear evidence that the student has taken the requirements obtained earlier in the project and processed them to get a suitable design. Therefore, markers must be able to see a clear link from requirements to design and where necessary observe how the requirements were processed. Markers should be wary of processing plans that say such things as "I will look at the requirements" or "I will analyze the requirements" as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same requirements they could apply the same processes and get the same or at least a very similar outcome.
8. Discussion of build process and design implementation
Reference: Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for a rational discussion as to what architecture, components, languages and tools and so on are needed to best implement the design. This discussion may also imply the various situation constraints have to be considered as well.
9. Application testing process and results
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers must look for evidences of a testing plan and a consideration of test results. Typically the plan and results are placed in the main project document in outline form with the details in an appendix. Often students will just discuss white or black box testing or regression testing or something similar but without any actual test plans or results – in such cases marks should not be awarded as these materials is considered common knowledge at this level – however brief references to it are permitted.
10. Implementation plans
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers should look for a comprehensive implementation plan – it need not be extensive or in minute detail but it should cover installation, user training, data conversion/loading, change over, user acceptance and hand-over.
11. Attributes of the project artefact (e.g. quality, reliability, etc)
Reference: none
The intended project application must be clearly visible and available to run directly from a disc or DVD. Markers are to award marks based on their perception of the general quality of the application if they were to put themselves in the place of a user. Assessment may then consider colour scheme, ease of use, operating instructions, presentation (does it look as if its finished), speed, etc.
Section D - Marks for Project Evaluation and Conclusions
12. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project application so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project application. The section is not intended for vague thoughts about the situation or application but a considered evaluation of the project application when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
13. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate. This is where one expects to find some information on what the student has learned, the way they work and the tools they used. It is often the case that students have very little idea what they did apart from being able to state vague activities such "look at" or "analyze" so without anything concrete to evaluate they resort to the routine and say "the survey process went very well" or "the UML modelling was straightforward" or else they simply ignore this form of evaluation. Evaluation of project practice is difficult because the student must ask searching questions related to process success and the notion of good and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way' or "what were my constraints".
14. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a an application was for eCommerce selling shoes it might be possible to ask what aspect of that application could be re-used to sell other product. It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

13. WORKBOOK 13 – FORM: PROJECT MARKING RECONCILIATION

The form shown below is included for reference only so that you can see how your project will be marked.

Project Mark Reconciliation Form		Final Agreed Mark (%)	
Name of Student			
Brief Project Title			
Name: Supervisor			
Name: Second Marker			
Name: 3rd Marker			
<p>Cause – in this box, describe, for each applicable section, why the marking disagreement occurred.</p> <p>Rationale – in this box, If a mark can be agreed, explain the rationale used to reach agreement. Please note that it is only necessary to agree the total mark for each section not individual category marks.</p> <p>Irreconcilable - If you cannot agree a mark leave rationale blank and it will be filled in by a third marker who will place a tick in the small square box.</p>

14. WORKBOOK 14 – SUPERVISION AND MARKING GENERAL GUIDANCE NOTES

1. **Presented Work** - Marker's are reminded that any marks awarded must be solely based on the assessment of work presented within the mark categories listed on the mark forms. It is not permitted to award marks for "hard worker" or "tried very hard" or "was a good student" or any similar observation as there are no relevant mark categories and this kind of criteria is almost impossible to evidence.

When an Engineering artefact is presented it should be viewed in action to ascertain the mark for "Attributes of the Project Artefact". The copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If this is not the case then markers must assume that there is no evidence for the application and set the mark accordingly.

2. **Word Count** – on the project submission form there is a space for a word count (excluding appendices) and if this is exceeded then it is indicative of a deliberate attempt to go beyond recommendations and you may therefore find that it leads to laboured descriptions or inclusion of irrelevant material in the project document and you should therefore mark accordingly.
3. **Structure** – mark categories do not necessarily represent chapters in a project document and so Marker's need to be aware that a particular project may be structured in a way that does not correspond to the sequence presented on the mark forms (though it is recommended to do this when possible). However, all the elements on the marking form must be visible in the work presented.

Although it is recommended that the mark form sequences be followed in the project document that does not mean that there has to be a chapter for each mark category. Students, therefore, should be encouraged to merge sections in order to produce a concise document. For example, it is perfectly possible and reasonable to merge the two evaluation sections and conclusions into one chapter as long as the relevant mark elements are still visible.

4. **Appropriateness** - any work presented must be within the prescribed subject area for the course. If a marker suspects that this is not the case then they should consult with the relevant course leader for clarification. In such accepted cases markers must regard the primary data and its processing as not being appropriate and mark with that in mind.
5. **Evidence** - the project report or appendix must contain sufficient evidence that the core project research work has been done (not the literature review). That is, in the case of study project a marker must be able to see the primary data collection appropriately presented (usually in an appendix). In the case of Engineering projects it must be possible to see a suitable requirement document or catalogue (possibly in the appendix). Once the primary data is visible then it must also be possible to see how that data was transformed into the intended project outcome.
6. **Literature Support** - when marking Literature Reviews their content must be seen to be focused on the topic area and address clearly the associated problem theme without any irrelevant material with the intention of offering a concise discourse that is focused, relevant, authored, measured, evaluatory and expressed as a dialogue. (see section 5.1)
7. **Grade tables** - markers must be aware of the criteria associated with awarding a given overall mark as they may be required to justify it to the UAB in terms of the criteria stated in the table shown below.
8. **Process** – when marking it is important that the process used to get an outcome by the student is visible in the project document. In practice this means that it is possible to perform the following trace: presenting problem, discussion of how problem might be resolved, suggested form of project outcome, research design and execution, generation of stated outcome, evaluation and conclusions – viz:

Engineering – typically, the process starts with a business related or technical problem theme leading to a research plan for the collection and discussion of requirements and their transformation into a suitable design and associated architecture. From this there should follow a build, implement and testing process with the whole project completed with suitable project specific evaluations and conclusions containing generalisations.

Study – typically, the process starts with a business or strategic IT related problem theme leading to a research plan for the collection and discussion of primary data and its transformation into an outcome that would resolve or go some way to resolving the stated problem theme. The whole

project is then completed with suitable project specific evaluations and conclusions containing generalisations.

Marks	Master's Level Grade Criteria
70 – 100	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Excellent work - able to express an original reasoned argument in a lucid manner by reviewing & critiquing a wide range of material. Original, critical thinking based on outstanding insight, knowledge & understanding of material. Material contributes to current understanding & is of potentially publishable quality in terms of presentation and content ▪ Wide reaching research showing breadth & depth of sources
60 – 69	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Clear, balanced coherent critical & rigorous analysis of the subject matter. Detailed understanding of knowledge & theory expressed with clarity ▪ Extensive use of relevant & current literature to view topic in perspective, analyse context & develop new explanations and theories
50 – 59	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Detailed review and grasp of pertinent issues & a critical contextual overview of the literature. Thorough knowledge of theory and methods & uses this to underpin arguments and conclusions ▪ Confidence in understanding and using literature
40 – 49	<ul style="list-style-type: none"> ▪ Demonstrates grasp of key concepts & an ability to develop & support an argument in a predominately descriptive way with valid conclusions draw from the research ▪ Familiarity with key literature which is cited and presented according to convention ▪ Logical & clear structure, well-organised with good use of language and supporting material
0 – 39	<p>FAIL – Some knowledge of relevant concepts & literature but significant gaps in understanding and/or knowledge. Little attempt at evaluation, conclusions vague, ambiguous & not based on researched material. Limited or inappropriate research. Deficits in length, structure, presentation &/or prose.</p>

15. WORKBOOK 15 – FORM: UNIT FEEDBACK REPORT

This form may be used by you to feedback to the University your experiences in the courses. It is normally sent to your tutor at the end of the course.

Unit Level Feedback – Delivery Evaluation for Online Units										FF.2.3		Page 1 of 1	
This student feedback questionnaire is intended to help students provide constructive feedback to the unit lecturer.													
Student Name (Optional)										Cohort			
Unit Name													
Lecturer													
Q	 Good					Place a ✓ to rate each factor from strongly disagree to strongly agree in one of the 5 boxes							
1						Chat sessions started promptly.							
2						Char sessions were structured usefully for learning.							
3						Chat content helped my understanding							
4						Chat Tutor handled student questions sympathetically							
5						Chat Tutor used helpful examples where necessary							
6						Chat Tutor answered session questions in a helpful manner.							
7						Chat sessions stimulated me to think beyond the material delivered.							
8						Chat topics were often related to real-world situations.							
9						Chat Tutor encouraged students to participate during the session.							
10						The Tutor was expert in the subject area.							
11						The written notes provided were helpful to my learning.							
12						The study pack Workbooks were helpful in my assessment preparation.							
13						The 5 milestone tests helped me to confirm my knowledge.							
14						Tutor responded in a timely fashion to discussion board questions.							
15						Tutor responded in a timely to my email communications.							
16						Tutor was sensitive to the problems of individual students.							
17						The assessed work stimulated me to think deeply about my project.							
18						Feedback on my progress was available.							
19						The topic approval process helped me think clearly about my project.							
20						Written assignment specifications were clear.							
						For Official Use Only							
General Comments:													

16. WORKBOOK 16 – USEFUL BAGeD WORDS

These words and their definition may be used to formulate your BAGeD idea is a research design

Account for - Explain and clarify something by giving reasons

Analyse - Resolve something into its component part, or examine critically and minutely.

Appraise - This is best thought of as something like forming an opinion about something. It might be quite simple such as forming an opinion as to whether something is good or bad but more often that not it's about forming an opinion about something after assessment or evaluation with regard to what can be done - so we might appraise whether a process for example should be left unchanged, modified or made redundant.

Assess - Determine the value of something. Similar to evaluation but it is often useful to think of evaluation as a qualitative process and assessment as a quantitative one.

Catalogue - This means to create an ordered collection of some sort where there is a logical order and the essence of the task is to enumerate and describe

Collect - This is very simple as all one does is to identify the data and literally collect it as you see it. So if I were looking for SPAM instances then as soon as I find one I just file the whole SPAM email away for later processing.

Compare - Look for similarities between one or more things.

Compile – similar to list but here the implications is you search many sources but in doing so having to make decisions in the process

Contrast - Look for differences between one or more things.

Criticise - Make a judgement, backed by a discussion of the evidence or reasoning involved, about the merits of theories, opinions, .

Define - State the exact meaning you are attaching to a word, phrase, idea, process etc

Describe - This may be used freely to describe in detail situations, events, opinions, feelings and so on.

Differentiate - Look for elements that would clearly differentiate between two or more things

Discuss - Explain something by giving two sides of the argument

Evaluate - In some cases one might want to look at events or people or processes in order to form an evaluation and that collection of (usually) small evaluations form our primary data.

Examine - Look carefully at the details of an argument, theory, or plan etc

Explain - this is about saying why something is. So one can describe an event but also explain why it occurred

Explore - You can use this word but we are always exploring so it must be used with care. Typically, in these cases one starts with a model of some kind and uses that to inform the exploration process. For example, we might have a theoretical process map and we use it to explore various working processes to see if we can find flaws or weaknesses and then those descriptions of flaws or weaknesses become our primary data.

Illustrate - Here one is trying to find a way to express in a very pointed way some situation or thing. So one might identify an instance of SPAM and then illustrate why it might be harmful so adding poignancy to the example you have extracted. Mostly, it is best to think of illustration as a way of giving an example but in that example you want to make just one clear point.

Interpret - The essence here is that one is typically observing something to describe it but also to find some meaning in what is being done. This is often used when looking at social groups or situations where it is not always obvious why certain actions occur

Justify - Show adequate grounds for decisions and conclusions and answer the main objections likely to be made about them.

Link - This is often a neat way of dealing with some types of data where you think there is a relation but the relation itself is not known with any certainty. One often finds this kind of activity evidence in a matrix formulation or representation.

Outline - Give the main feature or principles of an object, omitting minor details and emphasising structure and arrangement

Portray - This might be a useful verb if you were looking for types in a study. For example, if you were looking for people who get involved in illegal downloads one might want to portray them in some way.

Profile - This is similar to a description but it focuses on just the key points. For example, if we were looking for best practice in a situation then we might start by just profiling a given task – that is we outline the main steps and rationale to start with. The idea is similar to an outline but implies deliberate selection of certain aspects.

Represent - Sometimes you might plan to build a representation of some event as your primary data. For instance, if one was looking for security awareness in employees then of course one cannot "see" it or collect it as such. In these cases we must try to find a way of representing an awareness level or feeling and that representation forms our data.

Summarise - Give a concise and lucid explanation or account of something, presenting the chief factors and omitting minor details and examples

Synthesise - Resolve something into a whole from its component parts.

Exercise 004b.01a – Finding a Basic Activity Word Spotlight

This exercise and example sheet takes you through the whole of the research process. I have summarised all the things you need to know and provided some partial and some full samples. You must go to the partial example and complete them by looking at various elements and using them to write a research question. I will NOT be providing answers for all these samples (you will be doing that in discussion) and they are there for you to practice and use in your groups. Please don't avoid the work, you MUST get to a stage of knowing that what you have written is correct – if you don't know it's correct then you are not ready to do your own.

To start this off complete one or more of the examples and post the resultant Research Question into the discussion Board where I and others can comment.

Basic Activity Word – this entry will give a concise definition of the word
WARNING – in the Research Methods course the following key words have a defined meaning and you MUST study the relevant entries in the workbook. DO NOT assume that you know what these mean else you are likely to get into considerable difficulties.
Problem – this must define a single core problem for which you are going to find a solution route
Target – these are the effects that will be evident in the real world if the problem can be solved. It is permissible to list more than one effect but it is best to look for the principle one.
Outcome – this is the object you will generate as the final product of your MSc project. Possible outcomes are characterised by nouns so might be: reports, models, frameworks, policies, strategies, position papers, reviews, procedure description, best practice descriptions, dictionaries, lexicons, concordances, protocols, dossier, diagrams, charts, plans, etc.
Actor - It is normal when you define your outcome to say who the actor or actors are (meaning persons) who will use your defined outcome and to show that its use by them leads to the target effects
Activity and Data Spotlight – this is just about focusing on exactly the primary data that you need and nothing else. There are two parts really here: the activity: account for, analyses, collate and so on and the spotlight, the place where the data comes from
Research Question – this is a sentence expressed as a lucid question that connects the various features and expresses the direction of your research and summarises your whole project. The 6 elements are: interrogative, outcome, actor, problem, target and spotlight (data) - IO-APTS. The acronym IO-APTS is the correct order of these features in a sentence when the interrogative is “what” but for other interrogatives the order of features may need to change if you are to produce a valid sentence in English. Possible interrogatives are: Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, s/are, and can.
Research Method – choosing a method will depend on many factors such as: context, time available, skills available, practicalities, access, reason for the study, what kind of outcome you want, cost, nature of the study quantitative/qualitative, scale, control, and sensitivity of the data and so on. In this set of examples I choose a Research Method based largely on the basic purpose of the study. Basic purpose is usually assumed to provide as an outcome one of the following forms: express an understanding, an exploration, a description, an explanation, an improvement suggestion, build something or prove something. Common Methods and typical uses are: Case Studies – useful when trying to understand a situation or practice Vignettes - useful for exploring a situation in order to illustrate its major features Action Research – useful when it is desirable to improve a situation by working within it Experiments – useful when one is trying to prove or more usually indicate the truth of some proposition Quasi-Experiments – as for experiments but the experiment can only be simulated Surveys – useful when trying to describe a situation or effect Biographies/History – useful when one wants to explore a situation in order to replicates it or improve it Grounded Theory – useful when the area under study is barely understood but needs to be explored Ethnography – useful when one wants to describe a situation of some kind involving behaviour Requirements Gathering – useful when one wishes to build a real world object
Collection Protocol – this describes the means by which the primary data is actually collected: interview, questionnaire, observation, role playing, seminar, focus groups, document or record searching etc
Pre-Processing – this describes how the primary data in its raw collected form is processed into a structured collection of some kind.
Outcome Processing – this describes how the structured primary data collection is used to generate the intended outcome.

Account for - Explain and clarify something by giving reasons
Problem – inventory discrepancies leading to additional costs and delivery delays.
Target – reduced inventory cost and assured delivery times to customers
Outcome – revised inventory processes model
Actor – manager or managers responsible for inventory systems
Activity and Data Spotlight – to account for (activity) inventory discrepancies caused by current procedures (spotlight)
Research Question – what (interrogative) revised inventory processes model (outcome) can be used by inventory managers (actors) to make changes to the current system in order to reduce or eliminate inventory losses (problem) so that costs are reduced and customer delivery times assured (target) by exploring and illustrating features of working practices in the current inventory system that might account for inventory discrepancies (spotlight).
Research Method – in this case I am basically exploring this problem situation looking for illustrations of why discrepancies occur so that leads me to think that the method of Vignettes is the most suitable research model here.
Collection Protocol – record searching coupled with interviews .
Pre-Processing – this raw primary data collection will be pre-processed in order to structure the collection into the form of a catalogue of processes description each with a weakness assessment.
Outcome Processing – the catalogue produced in the pre-processing stage will be used to generate the outcome of a set of revised inventory processes using the company best practice model. This outcome will then be used to reform the way the inventory is managed and in so doing allow managers to generate the target of reduced inventory losses, reduced costs and assured delivery times.

Analyse - Resolve something into its component part, or examine critically and minutely.
Problem – delays and errors in generating audit request data
Target – reducing the time taken to generate the requested data and at the same time improve its accuracy.
Outcome – a report with recommendations
Actor - management
Activity Data Spotlight – to analyse (activity) the process used to extract data from the accounting systems for audit requests (spotlight).
Research Question – what (interrogative) recommendations (outcome) can be generated and used by management (actors) to plan for the enhancement of current audit request procedures in order to ensure that delays and inaccuracies (problem) are eliminated (target) by a close analysis the audit request protocols (spotlight).
Research Method – here my primary need is to understand the audit request process and so I will treat each request as a small case study .
Collection Protocol – a form of role playing will be used to duplicated and simulate the request
Pre-processing – the extracted audit data and the request will be pre-processed into a matrix which will be formed by listing the request, process used, data sensitivity, classification and auditors assessment of data quality...
Outcome Processing – using a process model the data will be used to form a mapping of requests to consequence and hence derive a report with recommendations to management on the effectiveness of current audit processes. This outcome will then be used by management to make an informed decision on the way audit request are handled in the future and in so doing generate the target of reducing the time taken to generate the requested data and at the same time improve its accuracy.

Appraise - This is best thought of as something like forming an opinion about something. It might be quite simple such as forming an opinion as to whether something is good or bad but more often that not it's about forming an opinion about something after assessment or evaluation with regard to what can be done - so we might appraise whether a process for example should be left unchanged, modified or made redundant.
Problem – poor IT staff utilization as is apparent in increasing staff cost and high consultancy fees.
Target – increased management awareness on current IT staff utilization practices
Outcome – an assessment report on cost savings and other benefits that might accrue from a better utilization of existing staff.
Actor - departmental managers
Activity and Data Spotlight – to appraise (activity) the staff utilization practices with regard to IT technicians (spotlight)
Research Question – How can (interrogative) effective utilization of IT staff (problem) be achieved after an appraisal of staff utilization practices (spotlight) in order to generate an assessment report (outcome) for use by departmental managers (actor) to aid and inform them in job distributions so that a reduction in costs can be achieved based on a maximization of existing staff's abilities (target)?
Research Method – my basic need here is explain the process so that leads me to believe that the histories method is most likely to give me a suitable research model.
Collection Protocol – document searching looking for example of utilization and how they were decided upon. It may be necessary to supplement this with linked interviews .
Pre-processing – the raw primary data will be catalogued into groups based on a manager's assessment of each employee focused on the current company standard payroll scales.
Outcome Processing – the grouped utilization practices and managers assessment will be analysed using an in-house workflow model to derive an assessment report of possible cost savings and other benefits that might accrue from a better utilization of existing staff. This outcome will then be used to brief departmental managers in order that the target of increased management awareness on current IT staff utilization practices is achieved in preparation for the bi-annual leadership meeting where this problem theme will be discussed.

Assess - Determine the value of something. Similar to evaluation but it is often useful to think of evaluation as a qualitative process and assessment as a quantitative one.
Problem – suspected under use of the new CRM system because some processes may have been inadvertently duplicated within the vestigial manual elements from the old system.
Target – increased effectiveness centred on full use of the CRM system
Outcome – list and rationale for the removal of suspected redundant processes
Actor – area managers
Activity and Data Spotlight – to assess (activity) the impact of effectively duplicate processes (spotlight) on the overall operation of the CRM systems in relation to potential cost saving.
Research Question – What (interrogative) rationale (outcome) can be found for the removal effectively redundant manual processes (problem) which can be used by area managers to reconfigure their CRM systems to increase its effectiveness and hence raise business productivity and reduce costs (target) by a assessment of the impact of suspected redundant processes on work flows (spotlight).
Research Method – there are expected to many processes involved and it seems appropriate here to use case studies because I need to understand why these duplicate processes co-exist.
Collection Protocol – document search to obtain the processes followed up by observation of the process assisted by interviews .
Pre-processing – the various duplicate or almost duplicate processes with classified into a list by their expected impact on overall system efficiency using a standard model based on the factors: utility, process cost, training commitment,
Outcome Processing – to obtain the outcome of a list and rationale for the removal suspected redundant processes that can be removed from the system each process will be reviewed by a seminar panel of relevant managers. This outcome will then be used by area managers to decide what vestigial processes can safely be removed without affecting company throughput and in this way generate the target of increased effectiveness centred on the full use of the new CRM system.

Catalogue - This means to create an ordered collection of some sort where there is a logical order and the essence of the task is to enumerate and describe
Problem – variable tele-worker productivity in software development
Target – assured worker productivity levels
Outcome – worker stress report
Actor – product project managers
Activity and Data Spotlight – to catalogue (activity) the stress effects imposed on tele-workers (spotlight) in a fast moving software development market.....
Research Question – How can (interrogative) managers gain assured productivity levels (problem and target) from tele-workers in software projects (spotlight) by commissioning a stress report (outcome) which will later be used by product project managers (actors) to plan an effective and balanced work schedule.
Research Method – here I want to explore this area so I am going to focus on Biographies and trace worker activities.
Collection Protocol - a questionnaire will be used to look for interesting or unusual candidates to interview and trace their CV and work activities by means of a form of document searching .
Pre-processing – the interview and document data be processed using common text processing ideas to classify and prioritise the main stress effects and presented as standardised short biographies .
Outcome processing – based on the biographies a worker stress report will be prepared for management with an assessment of possible productivity impacts. This outcome will then be used by product project managers to balance workloads based on the various stress factors uncovered in the report and hence generate the target of assured worker productivity level.

Collect - This is very simple as all one does is to identify the data and literally collect it as you see it. So if I were looking for SPAM instances then as soon as I find one I just file the whole SPAM email away for later processing.
Problem – customer complaints about delays in resolving problem via the help desk
Target –
Outcome –
Actor –
Activity and Data Spotlight – will be based on collecting (activity) help desk work requests and their associated actions (spotlight) that have been delayed for more the 48 hours...
Research Question –
Research Method – this is a potentially large population so for practical reasons I will use the survey format as I feel I am mainly trying to describe this situation.
Collection Protocol – effectively the protocol is document searching where we one extract the above information from the help desk log.
Pre-processing – classify the work requests into a prioritised list by: operative, system and action with a final assessment by the relevant manager of the main cause of the delay.
Outcome processing – the prioritised list will be used to generate an action plan to deal with identified common causes of delay with a view to revising the current help desk work model. This outcome will then be used by the systems team to focus the help-desk re-building process and hence it is hoped generate the target of a more efficient and reliable service.

Compare - Look for similarities between one or more things.
Problem - apparent mismatches between company needs and programming staff recruited
Target –
Outcome –
Actor –
Activity and Data Spotlight – to compare (activity) IT recruitment guidelines with current company tasks (spotlight) and their implementations
Research Question –
Research Method – since this is largely looking at what might be called historical data it seems worthwhile to use histories as the most suitable method
Collection Protocol – the essential task here is by a process of document searching as one compares the existing guidelines with the defined task specifications.
Pre-processing – none as a suitable list may be constructed at the collection stage by just using the guideline indices.
Outcome processing – the list will be processed to obtain a set of recommendations on a revised set of guidelines that better reflect company needs as found in the required tasks. The principle processing mechanism will be to use the existing task cost structures and the company staffing policy to arrive at the new guidelines . This outcome will then be used by team leaders and heads of department to focus their staffing needs in software development into an accurate and lucid job descriptions and hence generate the target of reduced recruitment costs and accurate selection of new staff to fit the required job profiles.

Compile – similar to list but here the implications is your are searching many sources and having to make decisions in the process
Problem -
Target –
Outcome –
Actor –
Activity and Data Spotlight – to compile (activity)
Research Question –
Research Method –
Collection Protocol –
Pre-processing –
Outcome processing –

Contrast - Look for differences between one or more things.
Problem - apparent mismatches between company needs and programming staff recruited
Target –
Outcome –
Actor –
Activity and Data Spotlight – to contrast (activity) IT re recruitment guidelines with current company tasks (spotlight)
Research Question –
Research Method - since this is largely looking at what might be called historical data it seems worthwhile to use histories as the most suitable method
Collection Protocol – the essential task here is by a process of document searching as one contrast the existing guidelines with the defined task specifications.
Pre-processing – none as a suitable list may be constructed at the collection stage by just using the guideline indices.
Outcome processing – the list will be processed to obtain a set of recommendations on a revised set of guidelines that better reflect company needs as found in the required tasks. The principle processing mechanism will be to use the existing task cost structures and the company staffing policy to arrive at the new guidelines. This outcome will then be used by team leaders and heads of department to focus their staffing needs in software development into an accurate and lucid job description and hence generate the target of reduced recruitment costs and accurate selection of new staff to fit the required job profiles.

Criticise - Make a judgement, backed by a discussion of the evidence or reasoning involved, about the merits of theories, opinions,...
Problem – apparent bottlenecks in the repayment system causing customer complaints and miss-payments
Target –
Outcome –
Actor –
Activity and Data Spotlight – to form a critique (activity) of each stage of the current repayment work flow (spotlight) with regard to IT usage....
Research Question –
Research Method – as my main aim here is to improve the flow in some way I have decided to use Action Research
Collection Protocol – observation based on the workflow definitions will be the main collection vehicle here.
Pre-Processing – this will look for outliers and clusters in the critique summaries and form them into a matrix in a prioritised order.
Outcome Processing – this will be in two stages. The first stage will look at outliers as they are normally indicative of underlying problems themes. The second stage will look at clusters as this implies similarity and that may point to where future IT deployments may best be sited. These two sections will then be used to generate the outcome of a set of process cycle synthetic metrics that can be used by finance managers to continually monitor the repayment cycle in the future and hence generate the target of functional repayment cycle which is reliable and verifiable

Define - State the exact meaning you are attaching to a word, phrase, idea, process etc
Problem – apparent transaction losses
Target –
Outcome –
Actor –
Activity and Data Spotlight – to define (activity) the state of each logged transaction within the scope of the current network transmission protocol (spotlight)
Research Question –
Research Method – this study will look at a large number of transactions and the essential method is therefore a survey
Collection Protocol – transactions data will be extracted automatically from the log by means of a software application. The software will also tag the various transaction types according to metrics defined in the literature to form a matrix of transaction definitions.
Pre-Processing – none as a structured collection will be available via the automate collection stage
Outcome Processing – the processing will automatically scale the data and display it in graphical form and of particular interest is transactions that might be regarded as outliers as they may be anomalous and point to processing sequences or other error types. Once the outliers are known it will be possible to produce as an outcome a report on verifiable metrics that can be used by monitoring software to predict which transactions are likely to cause process cycle difficulties and hence remedies can be sought in order to achieve the target of reduced transaction losses.

Describe - This may be used freely to describe in detail situations, events, opinions, feelings and so on.
Problem – lack of trust in security checking
Target –
Outcome –
Actor –
Activity and Data Spotlight – to describe (activity) differences in network penetration test results carried out over several test periods (spotlight).
Research Question –
Research Method – since we are essentially looking at historical data the method of histories will be used
Collection Protocol – document searching coupled with interview with systems administrators
Pre-Processing – the various discrepancies uncovered will be classified into severity levels and presented in a list format with administrator comments and a description of why it might have been missed on the previous test cycle.
Outcome Processing – Using the structured primary data set and the standard workflow model used in the testing suite attempts will be made to identify test scope factors that may have allowed faults to be overlooked and hence expose the network to unnecessary risk and hence generate the outcome of a revised scope of work and workflow model . This outcome will then be used by the outsourced security company team to adjust their testing suite so as to achieve the target of a security assured network.

Differentiate - Look for elements that would clearly differentiate between two or more things
Problem – poor IT utilization amongst middle level managers
Target –
Outcome –
Actor –
Activity and Data Spotlight – to explore the cultural milieu in which managers of an organisation exist by differentiating (activity) various cultural elements (spotlight) that are present.
Research Question –
Research Method – in this I feel I need to immerse myself in the day to day life of managers in order to understand how that milieu might point to how IT training might be used by them and this makes me think of the research method of Ethnography .
Collection Protocol – this is a slightly sensitive area so it seem best to use observation based on spending long sessions within the managers department coupled with informal interviews
Pre-Processing – the raw primary data will be in the form of a mixture of short and long notes plus some formal interview transcripts as well as some video and photographic information. With the rich information base an attempt will be made to extract typical ethnographic elements such as: behaviours, structures, functions, roles, politics and communication styles. The extracted data will be carefully organised into a concordance within these categories.
Outcome Processing – using the structured primary data collection I will attempt to match cultural themes found within a manager's department with a training mode that might be best suited for that culture. The basis of the matching will be to use the 5 stage learning model developed by Garlick (1999) so that in essence we link learning progression to its cultural suitability. The outcome will be presented as an IT training plan and used by the manager's forum to adjust their personal training portfolio so as to achieve the target of higher IT utilization leading to more effective middle level management.

Discuss - Explain something by giving two sides of the argument
Problem – non IT personnel are reluctant to engage in computer user training
Target –
Outcome –
Actor –
Activity and Data Spotlight – to discuss (activity) the function of IT training for non-IT personnel (spotlight).
Research Question –
Research Method – this is essentially exploratory and it therefore seems best given the wide diversity of opinion that is likely to emerge to use the survey method.
Collection Protocol – a presentation will be made in seminar sessions and this will be followed by open discussion . Although this is a survey I have chosen this method as I want it to be a learning experience for all involved as well so in effect I will be looking to see if the seminar assists in forming opinions.
Pre-Processing – the seminar discussion notes will be structures by looking for the usual text processing elements such as: common threads, outliers, labelling, etc and formed into a catalogue .
Outcome Processing – the outcome is to be a position paper outlining a new training initiative and this will be generated by looking at the elements identified in pre-processing and knowing these have emerged from a sample the attempt will be made to say what it might mean for the whole company - can it apply to the whole company, is there some important element in this theme that has much wider implications, is there a principle that can be established, can I construct a theory and so on. The position paper outcome will be presented to company and training management with a view to informing them of the general feelings and desires of the wider non-IT workforce so that the target of construction of future training plans and personal training portfolios that better fit with worker needs and aspirations

Evaluate - In some cases one might want to look at events or people or processes in order to form an evaluation and that collection of (usually) small evaluations form our primary data.
Problem – unemployed people's disappointment in their inability to locate an appropriate job
Target –
Outcome –
Actor –
Activity and Data Spotlight – to evaluate (activity) the elements functioning negatively and positively in job searches (spotlight).
Research Question –
Research Method – I am looking for the various factors that might be involved in job searching. Many of these will of course be well known such as qualification or skills but there may be many other that are not so obvious such as ethnicity, age, sexual orientation to name but a few. With this in mind I intend to explore this area looking for suitable illustrations of these factors and how they acted negatively or positively with regard to obtaining employment and so I feel the method of Vignettes is most likely to be valuable here.
Collection Protocol - My procedure will be to interview jobless 18-25 year olds (plenty can be found in job centres) in a defined inner city to collect illustrations of successful and unsuccessful job searches.
Pre-Processing – the interview transcripts will contain what amounts to suitable illustrations so these will be extracted and standardised based on a simple job seeker profile into a portfolio of successful and unsuccessful job searches illustrations.
Outcome Processing – using the illustration portfolio a protocol will be devised that when coupled with a standard job seekers profile can be used to enhance a web search for suitable employment opportunities. The outcome of a protocol and linked profile will be made available to job seekers and web job search system providers in order that the target of effective and satisfying web searches can be achieved.

Examine - Look carefully at the details of an argument, theory, or plan etc
Problem – frustration at the apparent time wasted on electronic correspondence
Target –
Outcome –
Actor –
Activity and Data Spotlight - to examine (activity) the various activities involved in the electronic correspondence process (spotlight) such as e-mail, fax, documents, photos, electronic forms, document and imaging process, accessing of images, routing/delegation functions according to the work flow process.
Research Question –
Research Method – there are several main areas and I need to form a clear understanding of the various technologies and processes so I will use the method of case studies and treat each communication area as a case study.
Collection Protocol – in this study I want to collect various communications samples and the practices associated with them in several areas and it seem best to do this by a series of observations and interviews with selected personnel from various levels in the company.
Pre-Processing – the collection phase will generate a large raw data set consisting of artefacts (samples provided in the interviews) and activity descriptions. It seems best therefore to organise these into a communication area/activity matrix linked to an artefact sample catalogue .
Outcome Processing – I think it best to process the matrix and catalogue to derive some suggested best practice description in the various areas and then by means of focus groups arrive at agreement on what can be called best practice and hence construct an outcome of a best practice portfolio in electronic communication and this can be used by individuals and training management to help ensure the target of communication being viable, efficient and satisfying to participants.

Explain - this is about saying why something is. So one can describe an event but also explain why it occurred
Problem – serious concerns in some departments over impacts on working practices of a proposed new land registry application
Target –
Outcome –
Actor –
Activity and Data Spotlight – to explain (activity) possible impact effects of a new land registry application system and database (spotlight) in common areas such as: cost, performance, user acceptance, etc
Research Question –
Research Method – the suggested method here is an extended survey as the system itself is quite extensive
Collection Protocol – there will be three main mechanism: document searching to establish expected benefits and then observations and focus groups to establish the consequences in the various areas
Pre-Processing – the observations and focus group information will be compiled under various headings using a standardised format and catalogued but will in large part be based on the companies stress model as the main aim here is to assess impacts but largely those will be people based impacts. The chosen method is to draw one or more Rich Pictures based on the catalogued information so that various perceptions can be shared and as a final step carry out another focus group where the pictures are examined and discussed.
Outcome Processing – the intended outcome will be generated based on a careful analysis of the catalogue produced in pre-processing. From the catalogue and the final focus group information a comprehensive impact report will be compiled that can be used to assist in planning by management for the implementation of the new system and hence achieve the target of alleviating genuine personnel concerns and preparing the organisation for a smooth transition.

Explore - You can use this word but we are always exploring so it must be used with care. Typically, in these cases one starts with a model of some kind and uses that to inform the exploration process. For example, we might have a theoretical process map and we use it to explore various working processes to see if we can find flaws or weaknesses and then those descriptions of flaws or weaknesses become our primary data.
Problem – loss of market potential for my company
Target –
Outcome –
Actor –
Activity and Data Spotlight – to explore (activity) the company business profile with regard to its fit within the modern global economy and the use of the Internet and eMarketing/eCommerce (spotlight)
Research Question –
Research Method – this is exploratory and in this case it seems best to think of the whole company as one case study area and the need to clearly understand its business profile.
Collection Protocol – there is potentially a lot of information here and it might be in diverse places including just in people's minds so it seems best to use interviewing coupled with document searching and then follow this up by seminar sessions to share perceptions via Rich Pictures.
Pre-Processing – The various interview transcripts and document extracts will be examined using normal text processing ideas to produce a detailed company business description (products, policies, structure, finance, Issues, IT infrastructure, etc) supplemented by feedback from the seminar sessions.
Outcome Processing – armed with the full business description and Rich Pictures there will be an open discussion with consultants about creating an outcome of a business case for an eMarketing/eCommerce outlet with the target of increasing the company's market potential based on using Porter's 5 forces model as a starting point.

Illustrate – Here one is trying to find a way to express in a very pointed way some situation or thing. So one might identify an instance of SPAM and then illustrate why it might be harmful so adding poignancy to the example you have extracted. Mostly, it is best to think of illustration as a way of giving an example but in that example you want to make just one clear point.
Problem – expressed dissatisfaction with the quality of delivery within a training organisation
Target –
Outcome –
Actor –
Activity and Data Spotlight – to illustrate (activity) how a student's acceptance and satisfaction in a training course (spotlight) are affected by the various technologies that might be used.
Research Question –
Research Method – this is a new area and I am not sure what sort of things will emerge so it is therefore largely an exploratory study and since I am aiming to find various factors that might be significant I think the Vignettes method is the most appropriate.
Collection Protocol – in this case I am looking for examples or illustrations of the various factors in action. It therefore seems appropriate to use both interview and observations of participation activities that occur during training.
Pre-Processing – the raw primary data will be in the form of simple illustrations of training activities and an assessment of the technology effects that were observed. This raw data will be processed to find a common catalogue of illustrations that explain technology acceptance and satisfaction levels and each illustration will effectively define a training factor.
Outcome Processing – using the catalogue of illustration and named factors a training model will be constructed that maximises both satisfaction and acceptance. This will be accomplished by using the standard model features and outline course learning objectives. The outcome will be used by trainers to re-model all course offerings and hence achieve the target of higher satisfaction levels in our course provision.

Interpret - The essence here is that one is typically observing something to describe it but also to find some meaning in what is being done. This is often used when looking at social groups or situations where it is not always obvious why certain actions occur
Problem – getting more value out of POS systems
Target –
Outcome –
Actor –
Activity and Data Spotlight – to be based on interpreting (activity) customer responses to kiosk/POS implementations (spotlight).
Research Question –
Research Method – given the large number of potential sample points here it seems obvious that a survey is the only feasible choice
Collection Protocol – the protocol will be a survey of customers by means of interviews to obtain data such as average age of buyer, degree of satisfaction, service speed etc. To balance this I will also obtain from the client such things as increase in perceived business value, improvements in customer relations, kiosk usage statistics etc.
Pre-Processing – the interview data will be processed using the usual text processing methods with some simple statistics and all this data will be structured into a matrix with the various factors identified during text processing – one matrix from a customer viewpoint and another from the retailer viewpoint.
Outcome Processing – once the matrices and statistics are available I will construct a report on the efficacy of this enhanced form of POS using the PESTLE (Political, Economic, Sociological, Technological, Legal and Environmental) model of analysis. This report will be useful to managers contemplating this technology as it may help in pinpointing what conditions within the market place must exist for it to be successful and hence lead to the target of getting more return on the POS systems.

Justify - Show adequate grounds for decisions and conclusions and answer the main objections likely to be made about them.
Problem – suggested productivity gains in upgrading to MS vista
Target –
Outcome –
Actor –
Activity and Data Spotlight – to attempt to justify (activity) a new function set (spotlight) based in expected productivity gains
Research Question –
Research Method – my basic aim here is to indicate (it is not possible to prove) the viability of productivity gains from an upgrade to Vista. It follows, that the essential method here is my means of Quasi-experiments because it is not feasible to install Vista on the live environment since that would imply the decision to upgrade has effectively been made. It follows that for testing to be feasible any possibly justifications must be made in a simulated environment.
Collection Protocol – the means here is simple data recording based on a series of Vista function tests. To carry out the tests a series of known common tasks will be formulated covering general topics such as searching, surfing, organisation (of directories and files), ..., and products based on covering Word, Excel and PowerPoint. The process will be to use the series of common tasks as part of a training exercise in Vista with several staff recruited to carry this out. The recorded data will be exercise timings, accuracy achieved and a reflective diary kept by each participant coupled with the participant and observed function justification (why it might be useful or more useful than that available currently)
Pre-processing – this will classify all functions tested and with various statistical calculations attached. The reflective diaries will be scanned for pertinent comments on each function. This will be structured into a catalogued report ordered by function.
Outcome processing – the catalogued justification report will be analysed from three viewpoints: the first will be utility (how well did the function perform), likeability (how well was it received by participants) and potential cost benefits in terms of productivity in order to generate a careful review and recommendation to management. This outcome can then be used to gain the target of an informed management on the expected gains/losses of the proposed upgrade.

Link - This is often a neat way of dealing with some types of data where you think there is a relation but the relation itself is not known with any certainty. One often finds this kind of activity evidences in a matrix formulation or representation.
Problem – inappropriate user behaviour in the use of their work based PC systems and networks leading to various undesirable side effect such as loss of bandwidth, virus infection, risk exposure etc.
Target –
Outcome –
Actor –
Activity and Data Spotlight – to link (activity) a security violation with a particular user behaviour (spotlight) - that will generate a primary data item (implicit here is that we also need a description of each violation and user behaviour).
Research Question –
Research Method – the basic method here is to use a survey instrument as these inappropriate user behaviours are thought to be widespread in the organisation and there is therefore a need to explain these actions.
Collection Protocol – search and extract violations descriptions from the log using a text processing tool. This is a sensitive area and one is unlikely to get good data by any direct means. However, interviews will be used to explore user behaviours in general.
Pre-processing – the violation descriptions will be examined in a seminar with experts to establish the behaviours that caused the violation. To do this a matrix of violations linked to user behaviour is formed with a violation severity rating based on violation extent: local to department, local to PC, local to a particular system, local to the intranet or global to the company. The interview transcripts will be summarised using normal document extraction methods and presented in tabular form to inform seminar participants
Outcome Processing - I need no to use the prioritised matrix to develop a security policy . Therefore I might search for an appropriate BS to guide me in the process or I might use a method called PLOT – but whatever I use it has to be such that it can be repeated by another person. The whole purpose of the process is that I can then draw up a policy that might help us achieve the target of eliminating or at least reducing these inappropriate user behaviours. The outcome will be presented to management for approval and then implemented by the IT department with appropriate training and technological means.

Outline - Give the main feature or principles of an object, omitting minor details and emphasising structure and arrangement
Problem - IT services migration time overruns
Target –
Outcome –
Actor –
Activity and Data Spotlight – to outline (activity) an engineer’s activity for each migration service (spotlight).
Research Question –
Research Method – this study examines past records of migration activities and it is about understanding them and the services they support so it seems best to think of this as case study but based on historic data with a number of migrations examined.
Collection Protocol – the main protocol is document searching to extract the necessary data via online status reports and these may be supplemented by interviews with engineers and/or the service providers.
Pre-processing - Once I have collected my primary data I will structure it as a categorized table with engineer activity and migration services noting cases where migration delays occurred. The table will be organised on a key activity idea where these key activities have been established by an examination of the project plan.
Outcome processing – a migration model will be used to process the categorized table to develop an optimised strategy for project control of key migration activities and used by project managers to get the target of reducing migration project overruns.

Portray - This might be a useful verb if you were looking for types in a study. For example, if you were looking for people who get involved in illegal downloads one might want to portray them in some way.
Problem – SPAM is junk mail and leads to high loading on infrastructures but this study will focus on the increasing level of complaints from users ranging from simple irritation to exceeded mail box quota lock-outs.
Target –
Outcome –
Actor –
Activity and Data Spotlight – to portray (activity) SPAM instances (spotlight) by extracting messages from various server logs.
Research Question –
Research Method – methods of SPAM prevention are well known and for this study to be interesting it needs to uncover something new that might help in the SPAM elimination battle. One such element might be to portray various kinds of SPAM perpetrators and to this end the study will explore SPAM messages in order to discover these portraits and so it seem best to use the idea of Vignettes
Collection Protocol – since we need to look at messages there is an inherent risk that they also carry elements such as a virus of some kind which opening the message might trigger. For this reason the SPAM message data will be extracted electronically using a tool which I will build so that the data can be examined in a secure environment.
Pre-processing – messages will be examined for common structural features such as: header, topic, sender, method of reply etc - to build up profiles of a typical SPAM message types. Once the profiles are available each message will be standardised and then presented as a catalogue . Using the catalogue a second stage of pre-processing will examine each standardised message to profile each message element: header, address, body and so on and that additional information will be added to the catalogue. The principal mechanism used here in this standardising process is the usual text processing ideas of looking for key words, labels and so on.
Outcome processing – using the SPAM message catalogue and element profiles the Cambridge profile model will be used to portray senders: introduction, personal needs, interests, skills, comparison with other similar profiles, message and profile match, conflicting indicators and message offering. These portrayals will be placed in a catalogue of SPAM perpetrators with commentary and used to get the target of informed users and also used by system managers as a guide to building SPAM secure systems.

Profile - This is similar to a description but it focuses on just the key points. For example, if we were looking for best practice in a situation then we might start by just profiling a given task – that is we outline the main steps and rationale to start with. The idea is similar to an outline but implies deliberate selection of certain aspects.
Problem – high levels of dissatisfaction with the very low revenues achieved through College fund raising activities
Target –
Outcome –
Actor –
Activity and Data Spotlight – to profile (activity) donors' giving habit/pattern/background and their associated publicity strategies (spotlight).
Research Question –
Research Method – in this case there are a large number of donors and the whole purpose here is to try explore what it is that drives them in their giving. It therefore seems sensible to use Vignettes as the most useful research model to use here because good and bad examples will aid in the exploration process.
Collection Protocol - Semi-structured interviews will be an effective vehicle to collect this data as it is of a sensitive nature. Preparation for these interviews will be by means on an analysis of donation records together with an examination of past publicity strategies.
Pre-processing – the interview transcripts will be pre-processed using the usual text processing ideas such as: labels, common themes, outliers, etc and from this the various illustrations will be constructed and formed into a PowerPoint Presentation
Outcome processing - the PowerPoint presentation will be used in a conference for senior managers to review/assess the fund raising illustrations. The conference will be split into groups, each group presenting its review findings at the close of the day and from this a position paper outlining a new strategic options generation framework with recommendations for an associated IT infrastructure will be generated. The process used to generate the framework will be a simple input/output model with the usual elements of performance, procedures, inputs/outputs, facilities and equipment and finally required skills and knowledge. The options framework can be used to derive IT supported fund raising initiatives the target of increased and assured College funding.

Represent - Sometimes you might plan to build a representation of some event as you primary data. For instance, if one was looking for security awareness in employees then of course one cannot "see" it or collect it as such. In these cases we must try to find a way of representing an awareness level or feeling and that representation forms our data.
Problem - management uncertainties and confidence regarding the proposed implementation of an EDM system.
Target –
Outcome –
Actor –
Activity and Data Spotlight – to represent (activity) the way information is managed (spotlight) currently being conscious that it may exist, be stored in, captured/archived and accessed in many forms including paper, microfilm, microfiche, tapes and CD.
Research Question –
Research Method – I need to get a close understanding of the document management issues and it seems therefore best to use case study approach here where I will think of each case as typified by an information medium. The study here will be by means of a light touch as I am not trying to gather requirement but only a representation of practices.
Collection Protocol – I anticipate that most of the document management practices are not available in written form consistently anywhere and I see no alternative but to use an observation and interview protocol in order to elicit the representations I need.
Pre-processing – using the observation and linked interview transcripts I will construct a catalogue of standardised representations of document management practices. The process itself will be to use the idea of best practice to form each standardised representation using: definition, control structures, design, distribution, accessibility, security classification, content type, associated policy/rules, status (contractual, regulatory etc) and issuing authority.
Outcome processing – I will use a type of spin-off model to asses probable impacts from which uncertainties may be gauged and hence confidence increased. I particular a modified form of the HAL Technology Impact Model with 4 elements: sponsoring agency, contractual, users, and other linked technology products. Using this simple model I should be able to use the catalogue of representations to asses what activities will need sponsorship, what activities will be spin-offs and where activities may be defused or unclear. Bases on the above assessment a report will be prepared to ensure the target of an informed and aware management board regarding the possible impacts in order that any new technology can be implemented with minimum disruption.

Summarise - Give a concise and lucid explanation or account of something, presenting the chief factors and omitting minor details and examples
Problem - over exposure of the corporation's data assets which may lead to data theft and increase reputation loss risk.
Target –
Outcome –
Actor –
Activity and Data Spotlight – to summarise (activity) the corporation's data assets (spotlight) by defining their value, criticality, sensitivity and legal implications.
Research Question –
Research Method - this research will solicit information on the data asset types, risk ratings and legal implications from the data owners and legal department so the use of surveys will facilitate the timely and standardized collection of this data.
Collection Protocol - Document Searching of recently completed Risk Reports for data value coupled with the use of interview scripts to define data, its criticality and sensitivity and to determine legal implications.
Pre-processing – The primary data will be scanned to complete a grid showing data types by sensitivity, legal requirements, reputation and other risk
Outcome processing - The data classification grid will be used to determine access permissions appropriate to a particular information asset based on an asset owner's assessment and be the basis for a data classification guideline for the Corporation's data assets protocol . The protocol will be used in corporate governance to gain the target of assured information assets.

Synthesise - Resolve something into a whole from its component part.
Problem – there is a concern that provision of IT services is not aligned with strategic organisational goals.
Target –
Outcome –
Actor –
Activity and Data Spotlight – to synthesise (activity) the various aspects of IT service delivery (spotlight) by examining delivered services to see what practices are involved.
Research Question –
Research Method – in this case I need to gain a thorough understanding of service delivery but at this stage I regard it as relatively unknown and exploration is needed and so it seems best to use the Vignette method to look for delivery exemplars or their opposite.
Collection Protocol – essentially this is about business performance issues and how performance is assured in part at least by IT service. With this backdrop in mind I will use interviewing to trace various IT services and their outworking and effects in business units. For this to be successful it will be necessary to obtain a list and description from the IT department beforehand of the various IT services commonly used in the organisation that might be regarded as business critical.
Pre-processing – based on interview transcripts I will extract perceived uses and needs and match this to the service definitions provide by the IT department. The collection of data will be expressed in matrix form and prioritised by a consideration of its essentiality to business but each entry will be a service delivery exemplar (positive or negative).
Outcome processing – using the list of exemplars I will use the ITIL service delivery model and a goal alignment model to recommend changes to the current practices so that IT service delivery matches needs so that IT managers can use it to get to the target of IT service goals being more strongly aligned with business goals.

Some of you seem to be getting their ideas in a muddle because they are striving to PROOVE something. In Research proving something is extremely difficult at the best of times and some things are impossible to prove. Writers going right back to the earliest times have grappled with the idea of proof and you will find the philosophical literature packed with books and articles on this one idea. We will be simple about it and start with the two, perhaps, main strands of thought: inductive and deductive reasoning.

Cause and Effect

It is as well when you read these notes to remember that everything one way or another has a cause. So if your accounting system malfunctions then there is cause or really a train of causes and effects: first effect is data input routine fails - cause of input routine failure programming error, causes of programming error is a mistake in the specification and so on.

Don't run away with this idea as in life there are many, many things where we can see the effects but have no chance of knowing the cause for certain: someone crashes into your car, you lose your wallet, you get short sighted and so on.

Research therefore is often at its root about seeing an effect and then looking for a cause. Once we know the cause we try to create something that we can use to remove the cause and so get rid of the effect we don't want by creating an effect we do want. For example, suppose the effect we see is misuse of IT resources for personal use (that is the effect we don't want) and let us for simplicity say that it is caused by people not knowing the rules of use so we can remedy this situation by creating a set of rules or a policy for IT usage and then when the rules or policy are used say by departmental managers we get rid of misuse (the effect we don't want) and instead we have productive use (the effect we do want).

It perhaps is worth noting here that we need two things: the outcome (rules/policy) and the actor (departmental manager) and that linking of outcome and actor will always be present.

Induction

This just means the inference of a general law from the observations of particular instances or sets of instances. What this means is that you notice something that happens and see that it happens often. It follows that you can infer or guess a general law from your observations. For example, you notice that people in your company tend to be more productive after IT training so you make a generalisation using induction and say "training in IT leads to personal productivity increase".

It is very important you understand that nothing has been proved here and all you have is an indication. It is not a proof because we cannot know what new IT tasks or technologies might occur in the future. One of the greatest modern philosophers, Popper, put it like this. "You can never accurately predict the future because it is impossible for men to know now what they, or others men, will know in the future". It follows that we are never possessed of the data that can allow us to make certain predictions about what may lie over the horizon based on our current stock of knowledge no matter how certain we feel about it.

Deduction

This just means inferring particular instances from a general law. So if for example we use Ohm's law we can predict with certainty the value of current if we know the resistance and voltage applied to a particular circuit.

In research we might think along either of these lines so for example we often set a hypothesis (a guess at general law) and then try to prove it. Alternatively we can go and collect data and by looking at the data see if we can work out what the law involved might be.

So if I were considering a link between personal productivity and IT training then I might take a deductive line and postulate the hypothesis (law if you like) "training always increases personal productivity" or I could take an inductive stance and just collect data and see if I can see (guess) what the "law" might be.

Comment on Induction and Deduction

There is no right and wrong approach here and it's a matter for you to consider what sort of outlook you are taking. Probably in technology we tend to take a more inductive attitude. Now it all may sound simple in the IT training case I mentioned above because using either stance one would collect more or less the same data but it will not always be that simple – for example supposed you were looking at the effects of IT system migration in a rapidly expanding company and project control methods used to manage it then it is now not obvious at all what the link between these two things might be so a deductive stance would be unsuitable here.

You might like to think of Sherlock Holmes the fictional detective of the Victorian era who was famous for making deductions. In one story called "The Cardboard Box" he visits a client and sees a photograph on the wall and deduces that the client has two sisters. If you like he used a general law: people have sisters and he uses that general law to deduce a particular instance of it: that his client has sisters. Notice here that such a deduction would not always be true but would be always reasonable.

You might further notice that this is not induction. It might look like it in that the photograph looks like data on which we might guess at some general law. This is not so however, since one cannot look at a photograph of three people and infer a law from it about sisters. Logically, we can say that many or most women have sisters therefore a particular woman probably has one. However, we cannot say a particular woman has a sister therefore all women have sisters. To put it more simply, we can say that if all boys are bad and Fred is a boy, therefore Fred is bad. But it is obvious we cannot say Fred is a bad boy therefore all boys are bad. In summary we cannot argue from the particular to the universal but we can argue from the Universal to the particular.

Proof

This means that the phenomenon we are looking at is always true. Now, in practice, proof might be constrained or unconstrained. For example Archimedes principle is unconstrained, meaning it is always true for everyone, all the time, everywhere and is accepted by all. But if we set up an experiment to try to prove that Google email is efficient – it will be constrained in that it is obvious that it is very unlikely to be true for everyone, all the time, everywhere and is accepted as true by everyone. In fact in this case it is severely constrained in that even if you managed to show statistically that it was true then at best one could only say that it applies to the sample used in the study. Additionally, using Poppers idea mentioned above it is obvious we cannot know what will happen in the future.

Notice that I say above that one characteristic of proof is that it is accepted by all but you would be surprised how often that is ignored. Just one ludicrous example will illustrate this, a student told me a story (it may be apocryphal) about an aged Saudi Arabian cleric who in 1977 issued a fatwa (a ruling) that the world was flat! So don't be surprised if people disagree with you even when the evidence seems overwhelming.

Indicators

This is where we talk about indicators - that is in the email study we might be deductive and infer or indicate that Google email is likely to be efficient for most users – that is indicators are not proof but generalisations made on the basis of some evidence (data) we might have. Think of it like this – suppose you invented a wonder pill that you claim would make you see in the dark. Now proving that it works for everyone, all the time and everywhere means that YOU are prepared to guarantee it is true. If it later turns out that for ME it did not work when I was driving my car at night and I ended up crashing and killing 40 goats, 2 chickens, a pedestrian and an onion salesman then I will sue you for £100M!

On the other hand we can be constrained and think in an inductive manner and say that "it has been shown to work in many cases" – that is all we are prepared to give is an indicator (a generalisation) because we have some evidence that it works but not a cast iron guarantee. You might like to link this idea of constrained to setting confidence intervals in statistics.

Sophistry

Much that you will read on the internet in particular can only be classed as sophistry that is clever but worthless argument. The Sophists arose as philosophers more or less at the same time as Socrates in ancient Greece and felt themselves to be very wise men who knew everything in contrast to Socrates who claimed he knew nothing. The Sophists it seems were not much interested in truth but only in winning an argument and many believe they in effect sowed the seeds of the demise of the Greek nation at that time. This may all have happened 2,500 years ago but their legacy lives on and the corrosive influences of their attitude is evident everywhere today and certainly in politics and religion.

As it happens I was discussing these ideas with a student a few days ago in this cohort and she pointed me to a site written by Dr Gary Miller. Dr Miller invites us to use his materials freely so I will do that to illustrate several things about proof. On this site he wrote many things which he regards are some sort of proof and he says it is possible to set standards for truth and talks about falsification tests. Here is one example of the kind of argument he uses.

(http://www.islamicinvitationcentre.com/articles/gary_miller/quran/Quran.htm#Intro)

An engineer at the University of Toronto who was interested in psychology and who had read something on it, conducted researched wrote a thesis on Efficiency of Group Discussions. The

purpose of his research was to find out how much people accomplish when they get together to talk in groups of two, three, ten, etc. The graph of his findings: people accomplish most when they talk in groups of two. Of course, this discovery was entirely beyond his expectations, but it is very old advice given in the Qur'an: "Say, 'I exhort you to one thing - that you stand for Allah, [assessing the truth] by twos and singly, and then reflect....'"

1. So we must look at this and see whether it can in any way be regarded as proof. We might easily observe straight away that there are no references and it is impossible for us to check what has been said as it's a hopeless task to find "An Engineer at the University..." He quotes the Qur'an but does not tell us the surah or the English translation it is taken from (or did he translate it himself or even just make it up). When you see this kind of extremely poor scholarship one has no alternative but to ignore Dr Miller's work entirely as it cannot be trusted. That does not mean Dr Miller is a bad person, all we are saying is that his work cannot be trusted.

2. You may also note that the quotation from the Qur'an is extremely short and that would make me wonder if he is just being very selective to try to make his own point – that is the quote in full might not support his conjecture so he ignores the bits that don't suit him. Again because we have no references we cannot easily check it.

Also notice that he adds something to the Qur'an "that you stand for Allah, [assessing the truth]" and so he perhaps forces an interpretation on the words "that you stand for Allah" but like any interpretation it is only one of many. Additionally, he assumes that it means assessing the truth of anything and it is almost impossible to see that the actual Qur'anic verses are saying that. Overall this looks like Dr Miller is being tendentious (the author simply wants to convince you of something and may use any means to do it) in the extreme.

3. What is he trying to prove here? That the Qur'an agrees with an Engineer's findings? That the Engineer has verified something the Qur'an has said? Is he offering an interpretation of the Engineer's finding or the Qur'an. We simply don't know for sure what point he is making.

4. It is interesting to note here that if this Engineer or the Qur'an is saying that working in two's is powerful he might like to recall that Socrates made the same observation, which he called his dialectical, with impeccable logic about 2,500 years before the Engineer was even born and about 1,000 years before any copies of the Qur'an existed. If you want to follow this up there is an excellent tape by Mark Forstater called "The Living Wisdom of Socrates", Hodder Headline Audio books which is a very engaging introduction to the teaching and life of Socrates.

This point is quite important and that is why we must read widely otherwise we may well think we have discovered something only to find that it is already known and published and we end up making an ass of ourselves because we have not prepared properly. At worst of course this can also look like plagiarism – to take my example a little further we could argue then that Engineer and the Qur'an both plagiarised the idea of Socrates – but of course we take the obvious solution to be that the Engineer and Prophet Mohammed had no knowledge of Socrates. Whilst we might easily allow that Prophet Mohammed had no knowledge of Greek thinkers (there were no great libraries or the internet 1,400 years ago) we are much less inclined to forgive this Engineer or Dr Miller for not knowing something about Socrates, perhaps the greatest thinker of all time.

In short what this example is saying is that you must be sceptical and careful with what people say and you must ask for evidence. Now of course in everyday life we don't question everything we hear or read otherwise life would be an impossibility but we must always be aware that things may not be what they seem and of course in research and what we read we do need to carefully question what it is because we want to be credible and not make a laughingstock of ourselves.

Ways of Dealing with Proof

There are a number of ways of dealing with this idea of proof and I shall just briefly review them.

Hypothesis

With regard to proof, many students like to write out a hypothesis. There are two stages: write the null and alternative hypothesis and then write down the two (usually) variables involved (dependent and independent variables). Unfortunately these two things are often not done satisfactorily. Let me illustrate.

A student wanted to prove something so he wrote a hypothesis that essentially said that there was a link between IT certification training and personal productivity in support roles. He then went on to define the variables as: Role of IT (independent) and Personal Productivity (dependent). Now this will ONLY makes

sense if you can quantify the variables productivity (which is quite easy) and 'Role of IT' which it seems cannot be quantified.

Now in research people tend to treat the idea of hypothesis and the notion of proof in two ways:

Formal - to set up an experiment with two samples one exposed to some effect and one not. So just to be simple I could set up a hypothesis based on say those who have been trained and those not and see if there is any difference in their productivity. This is quite complicated and difficult to do. Even then what would it mean if I could show that there was a link – would it be true/false for all time, everyone and everywhere or would it just be true/false for my sample?

Informal - Instead we could just have what might be called a tentative hypothesis that suggests that there may be a link and then use case studies to demonstrate this. Notice that we are NOT proving anything here only indicating/suggesting something might be true.

Setting Standards/Definitions

It is easily acknowledged that in normal life we can almost never get what one might call absolute proof. In courts of law for example they talk about the evidence being "beyond reasonable doubt" or based on "the balance of probabilities" – in other words you get enough information to convince (but not absolutely prove) you of the truth. This may be done in many ways but usually one lists the things one wants to see. For example, if I wanted to prove that Manchester United is the best football team in the world (they are not because everyone knows that is Arsenal!) then I might lay out my standard or definition for proof: no of goals scored, championships won, number of world class players and so on.

There are three problems with this approach: whoever you are talking to has to agree to your standards or definition, if I can prove it today will it still be true tomorrow and once one knows the standards it is all too easy to find the necessary evidence (one might often say manufacture the evidence).

If you want to think more about this you could look at the way Socrates 2,500 years ago uses this idea in his dialogues - one of the most famous was about beauty. Socrates was by all accounts ugly and he entered into debate with Critobulus who was a very handsome man. Socrates simply asked Critobulus what standard or definition of beauty he was using and Critobulus duly offered a definition which on the surface sounds credible. Socrates, then easily proved using the definition that in fact, contrary to popular opinion Socrates was handsome and Critobulus ugly - an obvious absurdity to any observer of beauty!

A vignette may help you here. I came across a true story of a man who had been married for many years but regularly had nightmares as to whether his wife really loved him. He was so bothered by this that he went to see a Church Minister and was told one way (standard/definition) to find proof (evidence) of love was to consider all the little things you wife does for you: wash you shirts, clear you shoes, cook your meals, look after you when you are ill and so on. You can see the "proofs" would be observable but is it really proof, will that man accept the standard or not, will it still be true in a year's time and if the wife knows the standard will she just manufacture the evidence? The fact is that one can never know the answer here absolutely and there will be many things in life that simply cannot be absolutely proved in any rational manner and all that can be done is to feel convinced.

Falsification

This means that a proof is like a chain with links – break one link and the chain fails. So in proof if you can find one contrary example then the proof fails. In life of course it is all too easy to just ignore contrary opinion or examples and go on only looking for supporting ones. No doubt you have come across many people like this (you or I may be one of them!!), no matter what you say to them they refused to be shifted from their own view even when the evidence is there.

Sometime you see this very strong idea distorted. Where you see this is with authors who try to show that X is untrue and then say that Y is therefore true. I am not talking here about a hypothesis because often there is no link at all between X and Y. As you may know from many of my examples, I am a student of ancient manuscripts and one argument I have seen many time is this one. The ancient Bible manuscripts are corrupted – that is over time the original manuscripts have been lost but copies were made but added to, changed and so on. Now it is easy to show that there has been corruption and no serious scholar would think otherwise. Now what many proponents of other religions and humanists have said is because that is true (the manuscripts have become corrupted) then their sacred book or idea is not. The argument is something like "I can show that Ford is a bad car therefore Volkswagen is a good one" or even more starkly, "you are wrong therefore I am right."

Note. Just in case you are worried there are such a large number of Bible manuscripts that it is in fact easy to reconstruct the original autographs. Incidentally, the same arguments have been used about the great Greek writers and Shakespeare.

Just to whet your appetite I might say that scholars who use the ancient manuscripts have what is called a “critical apparatus” or a process if you like for reconstruction of the original. Later I will be introducing you to various critical apparatus that you will be using to process data in your project. In technology we don’t usually say critical apparatus but instead we say Research Method or more simply problem solving method.

Proof by the Unexpected

Most often when we are working on a topic we have an expectation about the answer so that when we actually see it we feel sort of reassured about it. Now, sometimes we can be surprised and startled by an answer because it is just “too good to be true”. If one takes my hobby as an example, whenever an ancient manuscript is found we expected it to be corrupted or contain errors or emendations – why? Because before the days of the printing press it is just about impossible that a scribe could copy a document of any length by hand without making any errors or not being tempted to “correct” the manuscript or “improve” it in some way.

Sometimes the errors were deliberate because someone wanted the manuscript to take on his particular viewpoint or often it was done for gain. Shakespeare was often illegally “simplified” so that copies could be sold in the street or around theatres for profit.

Therefore if any one comes along and says their manuscript is not corrupted we automatically take a very, very sceptical attitude – it is just not credible and one tends to say it is probably a later forgery or at least there must be something wrong with it.

To give a technical example, some years ago I was researching software testing ideas and I had 5 sets of data based on different criteria. Scatter plots were used and the results from set 4 were just “perfect” and I was almost dancing with joy, a bit like Archimedes I wanted to cry out “Eureka” as I thought I had really uncovered a very important principle. However, the results were just “too good to be true” so that scepticism kicked in and I thought I have to check this. Sadly, what I had done was include just one sample point from test sequence 1 into the data for test sequence 4 and that one mistake had biased the results to such an extent that they were worthless.

Proof by Example

Many authors try argument as a way of proof. One often sees this in religion and politics but it is also present in many technical papers we see. The idea is that I present my view on something and then proceed to “prove” it by instancing examples that endorse its truth and often those who use this idea challenge you to find a contrary example.

I rather like this approach but one just needs to be ultra careful that we are not taken in by our own arguments and get to a stage where we just want to keep convincing ourselves that we are right and fail to see weaknesses in our own thinking. When you use this form your logic must be impeccable and you must get evidence that can be checked but always keep in mind that your arguments are almost bound to be constrained. Dr Miller’s page above is a useful one to look at as he rarely uses any sort of consistent logic or evidence and frankly seems to have lost all sense of scope and now sees everything and every example as supporting his own ideas.

Does it Work

It is always very strong when you can show that something works. That is you have a theory and although you perhaps cannot prove it in any absolute sense you can show that it works by citing examples. For example, some project management techniques are like this as we can see them working but if one is sensible one just recommends them as likely to work as no one would be willing to offer a guarantee that they always work no matter what the circumstances or project.

A Simple, Effective Time Management System

1. Getting the big picture: The semester calendar

This provides an overview of the semester. Fill in all significant events and due dates. This includes: papers, exams, presentations, organizational meetings, job or internship interviews, etc...

Filling in this information will give you a sense of when the “crunch” times are likely to be, allowing you to plan ahead. It will also ensure that you know when papers are due, the dates of exams, and when major projects are due.

2. Knowing your schedule: The weekly calendar

a) Determine the hours of the day that are not flexible or available for work. Write these down on the weekly calendar.

- class times, meetings, standing appointments
- eating, sleeping, exercising
- work, organizations, church, volunteer activities
- family time, social time

b) Determine how many hours each class takes in study / preparation time. List each class and estimate how many hours you need to devote each week (a good rule of thumb is to allow for 2-3 hours outside of class for every 1 hour spent in class).

Class _____ Hours/week _____

Class _____ Hours/week _____

Class _____ Hours/week _____

Class _____ Hours/week _____

c) Now begin filling in the available study time until you have accounted for all of the hours you estimated for each class. Keep in mind the principles of time management on the previous page, and create a weekly schedule for yourself.

Follow these time management guidelines:

Plan a schedule of balanced activities. College life has many aspects that are very important to success. Some have fixed time requirements and some are flexible. Some of the most common that you must consider are:

Fixed: eating, organization, classes, work, church

Flexible: sleeping, recreation, study, relaxation, socializing

Study at a regular time and in a regular place. Establishing habits of study is extremely important. Knowing what you are going to study and when saves a lot of time in making decisions and retracing your steps to get necessary materials, etc.. Avoid generalizations in your schedule such as “study”. Commit yourself more definitely to “study history” or “study chemistry” at certain regular hours.

Study as soon after lecture class as possible. One hour spent soon after class will do as much as several hours a few days later. Review lecture notes while they are still fresh in your mind. Start assignments while your memory of the assignment is still accurate.

Use odd hours during the day for studying. Scattered 1-2 hour free periods between classes are easily wasted. Planning and establishing habits of using them for studying for the class just finished will result in free time for recreation at other times in the week.

Limit your blocks of study time to no more than 2 hours on any one course at a time.

After 1 1/2 to 2 hours of study you begin to tire rapidly and your ability to concentrate decreases rapidly. Taking a break and then studying another course will provide the change necessary to keep up your efficiency.

Provide for spaced review. That is, a regular weekly period when you will review the work in each of your courses and be sure you are up to date. This review should be cumulative, covering briefly all the work done thus far in the semester.

List according to priorities. By putting first things first, you are sure to get the most important things done on time.

Eat well-balanced meals and get regular exercise. Take time for good meals and exercise. Healthy eating and exercise can dramatically improve your concentration, mood, and increase your energy level.

Double your time estimates. Most people tend to underestimate how much time a particular activity / assignment will take. A good rule of thumb is to estimate how much time you realistically think something will take and then double it. More often than not, this doubled estimate is accurate.

Creating a daily to-do list

A lot of students use a to-do list to organize their work. Many of these lists, however, do not increase productivity or decrease procrastination. There are three very important things that separate effective to-do lists from ineffective ones: making a new list every day, prioritizing the items on the list, and breaking items down into small pieces.

1. On the next page, write down everything you would like to accomplish tomorrow. This includes class readings, work on papers or problem sets, chores, errands, phone-calls, exercising, etc...
2. Now look at each item and, **if it feels too big to start, try to break it down into smaller pieces**. For example, don't write down "study for exam" or "write research paper." These items are huge and require many hours to complete – and we often put them off because we don't know where to start. Instead, break the studying down into "review chapters 2-5," "review chapters 6-10," "do six practice problems," etc... and the research paper into "spend 1 hour collecting articles at the library," "write an outline," "write introduction," etc... These items are much smaller, easier to start, and more likely to get done.
3. Next, **prioritize** this list by placing one of the following letters next to each item:
 - A** - Highest priority. Getting these items done tomorrow is very important.
 - B** - Medium priority. You would really like to finish / accomplish these things, but they can wait if you run out of time.
 - C** – Lowest priority. Getting these items done tomorrow is not very important.
4. Now think about when you will have blocks of time to devote to each of these items, making sure you take care of the 'A' items first and the 'C' items last.
Do this exercise daily: it is an effective way of managing your time.

To-do list for tomorrow

1. WORKBOOK 1. MASTER'S PROGRAMME OUTLINE

The Master's programme has two units of study: Research Methods and Project and the online programme notes together with this workbook pack cover all the information you need to complete it.

1.1 University Expectation

The University expects that when students submit work it is the very best they can do. In practice this will mean several things and all of them will be examined when work is assessed.

English – written English must be of a Master's standard and that means an IELTS score of at least 6.6 (or equivalent) is needed. If submitted written work is judged to be below this standard, students will NOT be allowed to progress to the project stage no matter what their actual language certification states.

Structure – work must be well structured and coherent. In practice students will most often work with a pre-defined set of headings and they must be used explicitly without deviation in their implied content.

Preparation – good work can only be produced if there has been adequate preparation. This will mean a thorough study of any and all references and exercises. Study does not mean a quick read through the notes or academic arrogance which says "I don't need it" or "I know all this stuff". This preparation also means working through the topic idea itself so that one becomes expert in a particular field.

Instructions and Guidance – all the work you submit will have to meet various standards in terms of layout and format and students are expected to following such guidance diligently.

Using other people work – all work submitted must be the student's own but within that work they may refer to the work of others but all material used must have proper attribution. Thus, if another author's work is copied, paraphrased or summarised it must be properly cited. Students need to understand that paraphrasing (putting things in your own words) and summarisation will amount to plagiarism if not properly attributed. This is a very serious matter and the rule with regard to copying is very simple. If 6 or more words are copied then the sources must be cited and if 10 or more words are copied without attribution then that is regarded as proof of plagiarism

Student's Own Work – the submitted work must be entirely constructed by the student and to do this it is necessary to weave into ones own ideas and thoughts the work of others. One may use the work of others to lend support to a proposition, or to include a definition or an explanation and so on. In other words it is not so much a question of how much of another person publication one uses but what one does with it in constructing ones own research work. In short scholarship is acknowledging and using the work of others whereas plagiarism is using the work of others and in so doing attempting to fool the reader into thinking it is ones own.

Respect – when writing one is doing it for another person to read and it's therefore a grave sin in those circumstances not to offer the very best one can produce.

Need - only quote, paraphrase or summarize when it clearly adds to what one is saying and it is not just common knowledge or obvious. The key task is to formulate ones own ideas, in your own words by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

1.2 Overview of Unit Assessment

The two units: Research Methods and Project are assessed separately and students must in each one gain at least a pass grade in order to qualify for a Master's award. The assessment artefacts are.

Research Methods Unit (15 Credits)

The Research Methods Unit will be taught over approximately 12 weeks and assessment details will be published to you early in the Unit. The assessments are as follows.

Assessment 1a - development of a project specification plus a short literature review

Assessment 2 - a coursework on statistics.

Project Unit (45 Credits)

The Project is an extended research exercise where students will be guided by a personal supervisor. For students who have passed assessment 1a, approved projects will start a few weeks after the end of the Research Methods Unit and last for at least 18 weeks. There is only one assessment as follows:

Assessment 1b – prepare a full research based project document based on the specification developed in assessment 1a. The details of what is required in the Project itself can be found in Workbook 9.

1.3 Research Methods Unit Assessment Overview

This unit of study requires about 150 hours of effort from each student and will cover research principles, research ideas, research techniques as well as statistics. Assessment details and due dates will be made available early in the study period for the Unit in WebCT.

1.3.1 Assessment 1a – Preparation, Literature Review and Project Specification Development

The first unit event will be related to the development of a project specification and is in two stages.

Part 1 – Project Proposal Approval (up to 10 marks) – when the Research Methods unit begins students need to gain approval for a project title/idea. The university will supply a list of ideas or students may bring one of their own as long as the related project outcome has a strategic business IT dimension, it is new work, it involved learning in IT and it is a Master's level activity. In the approval process students have to write a short submission to a set format and send it in a plain email to the Research Methods tutor whose decision is final. This process must be completed by the due date set in the Assessment 1a papers (normally about week 6)

Students are permitted ONE attempt to gain marks in each cohort at this stage and one of three outcomes is possible:

Approved – the submission, whilst not necessarily being perfect, meets all the above project criteria and the outline is judged good enough for the student to begin work on the specification. About two weeks after approval is granted a supervisor will be allocated who may assist you in finalising the project Specification.

Permitted – the submission has a suitable idea but its construction is judged to be of poor quality but the student is given the benefit of the doubt and is expected to make good in the specification. No supervisor will be allocated and final approval will be depended on the quality of the final specification.

Rejected – the work is received after the due date or submission does not meet the criteria for a project in this degree and a new topic must be chosen and a new application made. Most often this is because there is no Strategic Business IT, the project research is regarded as trivial or plagiarism is detected.

Part 2 - Online Self Tests – these will be available at set times for a set duration every week for the first 5 weeks. Typically 1 mark will be awarded for each test in which you score 65% or better. Students should note that missing any test for whatever reason means the recorded score will be set to zero automatically as there is no provision for taking the test at another time or by another method.

Part 3 – Short Literature Review and Specification Approval – based on an approved or permitted project proposal students prepare a short literature review and full project specification which must be posted into a WebCT drop box on or before the assessment due date. The Research Methods tutor will review the work and write a feedback report for each student. The specification and feedback report will then be placed before a University panel who will decide whether it is appropriate for a Master's level project. At the end of the specification approval process one of four outcomes is possible:

Approved – students with an approved project proposal will have their named supervisor confirmed. Students with a permitted project proposal status will be allocated a supervisor. The supervisor will be automatically sent a copy of the feedback report and specification. Approval will not mean that a specification is perfect and it is expected that students will take note of any feedback given by the Research Methods tutor or the allocated supervisor to further refine it.

Approved Conditionally – students with an approved project proposal will have their named supervisor confirmed. Students with a permitted project proposal status will be allocated a supervisor. The supervisor will be automatically sent a copy of the feedback report. Conditional Approval means that there are some significant concerns that must be addressed before work begins and students are expected to redraft their specification, based on feedback given by the Research Methods and in discussions with the allocated supervisor.

New Topic – this means that a student specification has been rejected in its entirety and another topic must be chosen and work must begin again by seeking approval for the new topic before writing a new specification for submission in the next available cohort. This action is most often used when the University decides that the work is trivial, or the work has no significant IT content, or the student has submitted a specification without gaining approval for the topic, or plagiarism is identified.

Plagiarism is Identified – no approval is given and the relevant student work is subject to review by a disciplinary panel. Plagiarism is a form of deliberate deception in order to gain advantage and will always be treated with the utmost seriousness and may even result in students being dismissed from the course.

1.3.2 Assessment 2 - Statistics Coursework

This is usually a set of questions and mainly deals with quantitative data. The submission date will be published to you.

1.3.3 Calculation of Research Method Unit Mark

The overall mark for the Research Methods unit will be calculated as a weighted average for assessment 1a and 2 with the actual calculation being $0.7 \times \text{Assessment 1a percentage mark} + 0.3 \times \text{Assessment 2 percentage mark}$ in which a pass is indicated by scoring 40% or more overall.

1.4 Assessment 1b - Master's Project

This unit of study requires about 450 hours of effort, guided by a University appointed supervisor and based on the specification developed earlier in the programme. The actual project document must be supplied in the form shown in section 9 of these notes and is expected to be of about 15,000 words maximum (excluding appendices).

Once allocated a supervisor, students will be asked on what date they wish to submit their project. The only rule regarding project activity is that it must last at least 18 weeks and no more than 2 years but it will be a matter for students to negotiate with their supervisor and the University to agree a submission date. Students are allowed to make small changes to the specification during the project process but they must be approved by the supervisor and must not amount to a change of the topic that was approved.

2. WORKBOOK 2. RESEARCH METHODS CHAT AND STUDY PLANS

This is a general plan for study for this course. Chat sessions are important because they are collective and interactive and typically focus on just one important feature of research and to get the best out of the course students need to prepare properly. That means reading the notes, doing the multi-choice tests that go with each chapter, studying the Workbooks and contributing if you can to the discussion boards.

2.1 Contact Mechanism

Contact with students is through email, discussion boards or chat. Email is very important and you should ensure that you use an Internet based service so that you can get mail almost anywhere. It is good practice to create an email account just for the duration of the course and a common choice is GoogleMail because the storage space is, for all practical purposes, unlimited. If you are not able to create a GoogleMail account let me know and I will send an invitation to you. It is important that only ONE email account is used for communication and that address is made know to the Research Methods tutor as follows.

Whatever, mail system you use it is advisable to set mail forwarding from both your WebCt accounts to your personal one to ensure that you get mail as soon as it available. It is also useful if students have a Skype or IM account as many tutors allow direct access if they are online. Skype is preferred since chat, voice and video are all catered for and during contact one does not get bombarded with advertising. Internet email services vary considerable but my recommendation is that you only use a service that:

- Provides a virtually unlimited storage capacity
- Guaranteed to work from almost any location: hotels, Airport, etc
- Allows you to set a mail forwarding address (most services do not so check this with care)
- Provide quality SPAM filtering, virus checking and is not on the SPEWS blacklist
- Allows POP redirection (so you can use Outlook and send from databases etc)

2.2 List of Workbooks Sections Available

Here is a list of all the workbooks in this pack. Students must read them as the course progresses and tutors will expect a committed familiarity with what they say.

No	Workbook Name	Comments
01	Master's Course Outline	General overview of course and assessment structure
02	Research Methods Chat and Study Plans	Lesson plans for the chat sessions and student study plan
03	Project Specification Notes and Examples	Shows what a submission should look like with some helpful hints
04	Sample Literature Review and comments	Shows what a submission should look like with some helpful hints
05	Literature Reviewing	Guidance on constructing a review
06	Major Project Elements	Notes on writing a clear aim and a set of corresponding objectives
07	Basic Research Methods Checklist	A list of several possible research methods for quick reference
08	Bibliographic Referencing Harvard APA	Notes on how to use and cite source literature
09	Writing Up a Research Project	Sample content outlines on how to write your project document
10	Project Submission Form	A checklist to use before project submission
11	Marking Form Study Format	A copy of the form use to grade your project submission for reference
12	Marking Form Engineering Format	A copy of the form use to grade your project submission for reference
13	Project Mark Reconciliation Form	A copy of the form to reconcile marks when markers cannot agree
14	Supervisor/marker notes and grade criteria	Use by supervisors and markers to assess project work
15	Unit Level Feedback	Form that allows you to give feedback on each unit you study
16	Research Methods Master Notes	Complete course notes as a pdf file (not in this pack)
Table 1. List of Workbooks		

2.3 Complete Study Plan

Students must work in a committed way for the 12 weeks during the Research Methods unit and submit the work required on the set dates – there will be no extensions given other than for sickness or other indisposition (in which case students need to complete an ECF and provide documentary evidence of incapacity). Failure to deliver on time without permission will mean that the student unit result will be recorded as a fail. For the whole course the timings in hours are approximately as follows:

Course Element	Time	Comments
Chat Sessions	25	Including preparation and summarizing the chat log
Regular Visit to Site	25	For email and discussion board
Study Notes/Text Book	35	Including making notes and doing the tests
Preparing Submissions	65	Including reading the relevant workbooks and topic details
Table 2. Overall Research Methods Unit Study Plan		

2.4 Recommended Timings for Completing the Research Methods Work

Please look at the following list of times for preparation and carefully plan a way through this unit using these estimates.

Course Element	Time	Comments
Statistics Questions	20	There will usually be 4 questions for you to work through.
Literature Searching	10	The key to a successful submission of the assessments is that ones mind is fully prepared with all the knowledge needed.
Task Description	5	Here students prepare a project proposal: the research question, the form of answer expected, the Basic Activity for Generating Data, data specification and decision on a research method.
Project Idea Approval	5	The format used for this can be found in the Assessment 1a description
Research Plan	5	Here students prepare a plan for collecting primary data. This is not literature searching, it is new and original research
Short Literature Review and Project Specification	20	A partial short literature review and comment is provided in Workbook 4. The Project Specification format is presented in Workbook 3.
Table 3. Coursework Submission Plan		

2.5 Recommended Five Week Development Plan

In this course students must write a project proposal as soon as possible using the format set out in Assessment 1a. However, the basic project idea must be developed and refined carefully and typically it will be done in the sequence shown in table 4 where items in blue are specific to Engineering and items in red specific to study projects. Typically this refining process start is week 3 of the course

There is NO short cut in this work and the standards are very high. The expectation is that you will read and study the notes, examples and exercises with dedication and care. Failure to study with care is usually obvious in the quality of the work prepared, so work hard and think through carefully all the steps below – there is NO substitute for thinking your own idea through. There are plenty of examples to guide you but these examples are not templates they are there to help you gain understanding and not as some sort of quick fix to the work.

If the University sees in your work that all you have done is copy the example substituting a few words here and there then it is very likely your submission will be rejected. The University is looking for students who are thoughtful and careful in their work and through a process of hard work each student must demonstrate commitment high standards – nothing else is acceptable.

Week	Work Recommended
2	<p>Topic Area Research – this is about thoroughly understanding the topic area in which your problem is set. For example, if one was looking on Inventory Management using IT in a fast moving retail environment. that is where your literature research efforts are to be directed. So one would look at inventory management itself, warehouse based systems, shop shelf systems, POS systems, tracking fast moving but small value items, restocking, forecasting, re-ordering and so on. The idea is that you take time to think of all the aspects of the topic and then you try to become knowledgeable in them. There is no short cut here and the work must be done thoroughly and with commitment.</p>
3	<p>Presenting Problem Definition – every project will be based on a real-world problem of some kind. Student must define the problem as accurately as possible and that will be the theme of this first work element. Notice the intention is to have just ONE problem definition. (See Workbook 6 section 6.2 and 6.5)</p> <p>Target – this is the intention of solving the problem itself – that is what real-world benefits will result. For example, the problem might be about accuracy in inventory records and that would imply that if we can find a suitable project outcome that can be used to alleviate that situation then it will results in the target of for example reduced inventory costs. Problem and target are two side of the same idea. (See Workbook 6 sections 6.3)</p> <p>Research Question – here one tries to encapsulate the problem definition and ones theorising into a concise and lucid question that will form the focus of the research effort. (See Workbook 6 section 6.7 and 6.9).</p> <p>Theorizing based on the problem Theme – here one theorises about possible causes of the problem and corresponding solutions. In the case of inaccurate inventory records we might theorize solutions as being based on: production of a training plan for staff, feasibility report on possible use of technology, development of a sales policy and so on.</p> <p>Project Outcome Form – during theorization choose what might be regarded as a best solution and this becomes the single outcome intended for a project. For example, if we take the problem mentioned above of inaccurate inventory records then a project outcome could be a feasibility report on the use of RFID as this might be seen as a way of solving/partially solving the stated problem. (See Workbook 6 section 6.4 and 6.7)</p>
4	<p>Primary Data Definition Outline – the primary data definition is affected by means of the BAGD and it needs to be focused on the problem definition and the expected form of answer. (See Workbook 6 section 6.6, 6.8 and 6.9) In Engineering projects the outcome will be an application of some kind and that needs to be described.</p>
5	<p>Aim and Objectives – in the aim and objectives you sharply focus ones project by stating the means whereby one gets the major project outcome by a series of minor ones in order to achieve the project real world target. Of particular significance here is that the distinction between a project outcome and a project target is thoroughly understood. (See Workbook 6 section 6.11)</p>
6	<p>Research Design – this is the core of any project and it is the place where one expects to see serious and consistent thinking about how the presenting problem is to be resolved by collecting and processing primary data in order to generate the expected project outcome that will eventually lead to a real-world benefit called the project target. There are three elements as follows. (See Workbook 3 section 3.2, 3.3, 3.4 and either 3.5.1 or 3.5.2 as appropriate)</p> <p>1. Research Method Selection – this is an overarching framework used to guide and control the research effort. There are many Research Methods and it is necessary by a process of logic based on ones Research Question and it primary data needs to select and justify a suitable method. For Engineering projects the research method is focused on collecting application requirements. (See workbook 7)</p> <p>2. Design of Primary Data Collection Plan – based on the Basic Activity for Generating Data which focuses on the core data needed and then that basic activity surrounded by a process that allow reliable collection of the primary data. (See Workbook 3 section 3.5.2). For Engineering projects the plan is based on the outline application proposal which focuses on the core requirements and outlines a process or processes that allow reliable collection of the requirements. (See Workbook 3 section 3.5.1)</p> <p>3. Design Primary Data Processing Plan – with a collection of primary data in some suitable form one can apply some processing to it in order to arrive at the expected project outcome. Typically this might be statistics if the data is quantitative, various forms of text analysis or diagramming if it is qualitative. (See Workbook 3 section 3.5.1 or 3.5.2)</p> <p>For example, if one conducted a survey on the effects of SPAM on personal productivity then this might have been done with a questionnaire with say 20 questions. Now processing each question and drawing charts and graphs is NOT the same as explaining the effects of SPAM on productivity – to do that one must consider the whole survey where each question would be a dimension of the problem space. It follows that typically one pre-processes the data collection in some way and later using the results of that pre-processing we further process the data to get the intended outcome</p>
Table 4. Specification Elements Work Plan	

2.6 Critical Reflection

Students must expect to go back and forth over their work because as knowledge and understanding grows one will inevitably see that some of one's earlier work was incorrect or not as clear as it could be or maybe it can be improved in some way. This revision strategy is very important as a common fault with research work is that it often lacks consistency because there was no serious reflection on earlier work.

2.7 Chat Session Profiles

The following is a simple guide as to what students will be covering in the online chat sessions. These sessions are extremely important as they are usually interactive and are based on using examples. The research Methods Unit will involve a chat session roughly once every week – half these sessions will be based around the notion of research methods and half based on statistical processes.

2.7.1 Chat Session 1 – Setting up a Project?

This chat session will be a discussion of what is meant by research. The chat will focus on the idea of a presenting problem, target and outcome as the basic project building blocks. From this the chat will move to discuss a framework to surround a research project and a look at some of the core techniques that must be mastered. To prepare for this chat read Workbook 1 and 2 and Workbook 6 section 6.2 to 6.6.

2.7.2 Chat Session 2 – Refining a project Idea?

This chat will take the form of a discussion on how a project idea is explored and focused and a full example will be used followed by an open discussion and questions from students.

To prepare for this chat, students should be familiar with the title approval format shown in Assessment 1a and the specification examples and notes shown in Workbook 3 sections 3.5.1 and 3.5.2. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea. Of particular concern in this chat is the notion of presenting problem Workbook 6 section 6.2 and form of answer (project outcome) in Workbook 6 section 6.3 and 6.7, Basic Activity for Generating Data Workbook 6 sections 6.8 and 6.9. Students must work hard on these three ideas if they are to form an acceptable project specification.

2.7.3 Chat Session 3 – Research Method and Research Designs

In this session a research design will be developed based on a personally developed problem definition, research question, form of answer and Basic Activity for Generating Data. To prepare for this chat students should be familiar with the title approval format shown in assessment 1a and have studied the specification examples shown in Workbook 3 sections 3.5.1 and 3.5.2 as well as the associated notes in section 3.1. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea.

2.7.4 Chat Session 4 – Literature Reviewing and Working in a Scholarly Manner

In this session some examples of student work and how they write down their ideas will be examined based on scholarly principles. This will be followed by looking at a process that applies equally to what one writes and what one reads. The remainder of the chat will examine several excerpts from student work that exhibit common faults. To prepare for this chat read workbook 8 on citation styles and bibliography, chapter 4 of the notes and Workbook 5 and it might be useful to read through the sample short Literature Review in Workbook 4. In addition, it will be useful if one look at one's own way of using primary source materials and find some examples that are good and bad.

2.7.5 Chat Session 5 – Aim and Objectives

This chat will focus on how to write an aim and a set of objectives based around a problem definition and a Research Question. To prepare for this session read Workbook 6 sections 6.11 and Workbook 9 section 9.6.3 but also consider one's own project idea and what might be suitable in that case.

2.7.6 Chat Session 6 - Open

This chat will look back over the course and typically review faults that arose out of the assessment of the project specification. This will be supplemented by a discussion as to how various project elements: title, research question and Basic Activity for Generating Data, aim (not aims) and objectives are constructed but focused on the basic Activity for Generating Data.

2.7.7 Extra Chats - Open

Normally, each week there will be an open chat on Sunday at 1400-1500 where students may bring their questions, comments, concerns or grumbles. These are useful sessions but only when students come prepared with items that they need to discuss. These are not teaching sessions so the tutor will have nothing to say unless students come prepared with questions and are willing to participate.

3. WORKBOOK 3. PROJECT SPECIFICATION NOTES AND EXAMPLE

This section contains some guidance notes and sample completed project specifications - please consider them carefully. Do NOT copy them blindly – they are just for guidance and students must write their own in a way that matches what they want to do. The aim of the specification is to state a project plan as clearly as possible so one needs to be concise and precise.

3.1 Project Styles

In projects two styles are commonly found. There are some restrictions on these two forms depending on what programme you are on but the Tutor will advise on that issue. Briefly the two styles are as follows:

Engineering – here you design and build a software application, create a system design etc.

Study – here you design a research program to collect primary data in an attempt to find an answer to an interesting question. For example, one might investigate whether cascading styles sheets lead to simpler accessibility or you might evaluate the role of email management in business success.

3.2 Specification and Design

The following notes and samples for project specifications may help you prepare your own. However, it is important to think of it as being primarily a design for your project. The specification is essentially in three parts although it is not presented in exactly this sequence:

Preparation – this is not explicit in the specification but implies that you have thoroughly reviewed the literature at least to the depth of feeling confident that you know enough about the project topic to define and gather data. Implicitly, the University will look at your use of the literature and reference list to assesses how prepared you are for this work at this level and on this topic.

Background – this is about you setting the scene and defining a problem and then focusing on that problem with a Research Question, aim and a set of objectives.

Research Design – this is the culmination of the specification where you set down your detailed design for defining, collecting and processing primary data to get your stated form of outcome. It is very important to realise that this is a design and without a sound design things are likely to go very wrong.

In summary, one needs to think of the whole processes as starting with a problem definition and ending with a solution (your project outcome) and the element that connects these two things is your research design. It follows that unless you have a good design you will not be able to get from your problem to your outcome and that will mean your project fails.

3.3 Project Specification Headings and Formatting

All the following main headings and subheading must be used and students must not introduce others. As these guidance notes are read it is advisable to also look at the relevant examples in section 3.5 so that one can clearly understand what is being said.

3.3.1 Specification Header

Make sure all your details are entered correctly otherwise work may be misfiled or rejected because we cannot ascertain whose work it is.

3.3.2 Project Title Construction

Project titles must make clear sense in English and not be overlong. See Workbook 6 section 6.13.

3.3.3 Specification Intention

This element is to be a simple statement regarding whether there is an actual real world client for the outcome of this project or if it has some other purpose.

3.3.4 Project Task Description

The main function of this section is to explain what is going to be done using the suggested headings below and as shown in the sample. The headings are intended to be precise and if students ignore or change them or use them for any other purpose the work will be rejected. The actual selection of headings will depend on the type of project: Study or Engineering.

Engineering Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct an Engineering project task description and must expect to go over them many times before a concise and useful description is formulated. For Engineering projects please note that a functional description means that one says what the application will do for the users and not how it might be built or what architecture is involved.

Situation Overview – express here a concise and high level description of the existing or proposed application area.

Presenting Problem Definition – a concise definition of some real world problem related to data processing of some kind. This is an important step since unless one can clearly see what the problem is then any solution suggested may be deficient in some way. In most cases the problem definition in engineering projects is related to elements such as data availability, searching, access speed, storage, processing, accuracy, sharing, reporting, entry, updating, deletion, control, security, volumes, segregation, consistency, worker efficiency, process systematization, communication and so on. For the purposes of writing a specification the expectation is that students will focus their problem definition on one major aspect of the application scenario. See Workbook 6 section 6.2 and 6.6.

Real-World Target – a summary of the real world effects that are expected if this problem can be solved or partly solved.

Application Proposal – expressed as a concise description of the main system functionalities. When describing the main functionalities it should be done at a high level and it is recommended that they are all coherent and there should be no more than 10.

Ethical Overview – express here a concise review of any ethical impacts of gathering the primary data, processing it or system usage.

System Architecture – a concise description of the major or main architectural elements of the proposed application

Strategic Value – expressed as a concise argument that the application is able to deliver to the stated problem definition.

Study Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct a study project task description and must expect to go over them many times before a concise and useful description is formulated.

Project Topic Area Overview – a concise description of the topic area aspect being covered.

Situation Overview – a concise, high level description of the context in which the research is set.

Presenting Problem Definition – expressed as a concise statement of the single underlying problem leading to this study. This is an important step since unless one can clearly see and define what the problem is then any solution suggested may be deficient in some way. Study projects look at an aspect of strategic business IT and that might cover technology effectiveness, IT investment, user acceptability, development or improvement plans, feasibility studies, legacy systems and so on. See Workbook 6 section 6.2 and 6.6.

Real-World Target – what desirable real-world benefit is likely if the stated problem can be resolved or partially resolved. (See Workbook 6 section 6.3)

Research Question – expressed as a concise question that captures the problem definition and the real-world target. See Workbook 6 section 6.7 and 6.9.

Personal Theory – expressed as a concise and focused rationale regarding what an answer might be to the Research Question. See Workbook 6 section 6.5.

Intended Project Outcome – write a concise statement that expresses the expected major project outcome as it arises out of the stated problem definition and your personal theory and would be an answer to the Research Question. See Workbook 6 section 6.4, 6.7.4 and 6.9.

Strategic IT Value – here it is necessary to discuss ones intended project outcome and show that it is or leads to a Strategic Business IT impact that could eventually resolve the stated problem definition and hence generate a Strategic Business IT value. See example in Workbook 4.

Ethical Overview – a concise review of any ethical impacts of gathering the primary data, processing it, presentation or usage of results in the form stated

3.3.5 Overall Project Aim

This is a vital point in the specification because in a very concise manner a researcher brings together in one aim: the main project **activity** to get a stated project **outcome** as well as telling us what **data** is the focus of the activity and finally what the purpose or **target** for the project outcome is in relation to real-world problem resolution. It is essential that you fully understand these four elements as described in Workbook 6 section 6.11, 6.11.1 and Workbook 9 section 9.6.3.

3.3.6 Set of Project Objectives

To meet an overall aim it is necessary to achieve a number of milestones indicated by a set of objectives generating minor outcomes. Objectives can be hard to write and it is expected that there would be between 3 and 6 of them. See Workbook 6 section 6.11 and 6.10.2, Workbook 9 section 9.6.3.

3.3.7 Research Design

The Research Design is about the core elements that generates primary data and processes it into the form of answer expected (your project outcome). The Research Design is divided into two phases.

Design for Collecting Primary Data – a process or processes used to define and create a primary data collection. It has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the actual data and present that data.

Design for Processing Primary Data – a process or processes used to manipulate the collection of primary data to get the form of answer expected.

A useful analogy for a Research Design is that it is like deciding that you want a sponge cake and then working with a shopping list (a list of primary data that you want) to collect a bag of ingredients (collection of the listed primary data). Once we have our ingredients (primary data) we use a recipe to prepare and mix them (pre-processing the primary data) ready for the final processing step to bake the cake (like generating your form of answer). To reverse the analogy, if you were going to make a cake you would not walk into a shop and just pick up a random set of ingredients and then mix them all together into some muddle, bake it and expect a cake to emerge - no one but an idiot would do that would they?

The suggested headings to use are as follows and you are recommended to use them carefully in a step by step manner to construct a research design. You must expect to go over them many times before a concise and useful design is formulated. In the examples I have added the step numbers for clarity but you do not have to do that in your own work as long as all the elements are present.

Engineering Projects Research Design Format

Research Design Phase 1 – Requirements Collection Process

This phase is concerned with a process that generates a reliable collection of primary data which in an engineering project will be a set of requirements. See Workbook 7 section 7.10.

Define – here one bases the definition of requirements on the outline proposal document.

Location – state where or from whom the requirements can be found.

Collection Protocols – here it is necessary to select appropriate collection protocols such as: interview, observation, records searching and so on needed to collect the requirements under the standard four headings: Functional, Non-Functional/Performance, Technical and Usability. See Workbook 6 section 6.6.1.

Requirements Presentation – the requirements data once collected will typically be presented as interview transcripts, notes and copies of documents and lodged in the project document appendix as a kind of requirements catalogue.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulate it to get a design for the application. This is in two sections.

Overview – show how the various requirements are expressed in a design.

Specific – in any design there will be aspects that have no obvious means of expression and such aspects are typically written as a list.

Study Projects Research Design Format

Research Method – make a selection and write concise rationale for its use. See Workbook 7.

Research Design Phase 1 – Primary Data Collection process

This phase is only concerned with generating a reliable collection of primary data and is based on the Basic Activity for Generating Data but to be it has to be surrounded by a complete process.

Basic Activity for Generating Data – a concise description of the activity that forms the core of the primary data collection process. See Workbook 6 section 6.8 and 6.9

Primary Data – outline primary data items to be collected. See Workbook 6 section 6.6.

Location – a concise description of where the primary data may be found. In practice it may come from almost anywhere including extraction from existing secondary sources.

Collection Protocol – a concise description of the actual collection procedure which may be based on one or more of the following: interviews, questionnaires, observation, roles playing, document analysis and so on. See Workbook 6 section 6.6.1

Primary Data Presentation – expressed as a concise description of the way in which the primary data will be presented.

Research Design Phase 2 – Processing and Presentation

This phase is only concerned with a processing the collection of primary data in order to get the expected project outcome.

Design of Pre-Processing for Primary Data Collection – concise description of the processes applied to the raw primary data collection to generate a refined collection of primary data structured in a fashion that makes it suitable for generating the intended project outcome. (Workbook 6 section 6.6.3) (Please note that this step will not always be needed)

Design for Primary Data Presentation – presentation of data collection generated from the pre-process step - if that step is not needed just a presentation of the primary data.

Design for Generating the Intended project outcome – here the primary data collection (pre-processed if necessary) is used in some algorithmic or heuristic fashion to generate the intended project outcome.

3.3.8 Logistics and Tools

In this section the practicalities in terms of tools and time need to be considered. It is only necessary here to state things that are specific to this project, so it is not required to say things like: the library, Word, Excel, paper, pen, SPSS and so on as these are common and almost always available everywhere.

3.3.9 Outline Content List for your Project

This should be detailed enough to ensure that there is a clear idea of the final structure of the project document. Please be careful with the essential elements as indicated on the marking forms since if they are omitted a significant number of marks may be lost in the final project. See Workbook 9 table 6 and section 9.3.5 where typical chapter and section headings can be found. Workbook 11 or 12 (marking forms) need to be consulted so that no essential elements are omitted

3.3.10 References

This section is used to assess how well a student has prepared for the project activity. The University will want to see that the reading is current, comprehensive and focused on the topic area. It is expected that work in the specification will be supported from the literature particularly in the outline description and research method sections. Unless the literature is seen to be used in the various sections of a project specification it may not be approved although it is not expected that one cites from every book in a reference list. See Workbook 5 and Workbook 8 and make sure citations are in the Harvard APA style.

3.3.11 Project Plan

The plan must be developed by looking at ones contents list and considering what activities are necessary to generate the various project objects. Aim for around 12 to 20 activities lasting at least 18 weeks with any suitable start date. A project activity is something that is significant and requires planning and monitoring. So for example:

Prepare Metric Program – this is clearly a significant activity that has to be planned and monitored and so properly part of the plan

Select an Organization – this is an activity and might be important but it is doubtful if there really is a significant process involved here that has to be planned and monitored.

Outline Implementation Plan – this is not an activity so should not be in the plan.

The University will examine each plan and will want to see that it is focused on the project – the implication here is that it should be possible to see that a given plan supports a particular project idea not juts a copy of one of the samples or is so generic it might apply to any project.

3.4 Testing Your Research Design

A design must amount to a logical plan that takes a problem definition to a description to the expected outcome that will resolve the stated problem. The following are a useful check that a plan is sound.

Practicality – consider whether one has the resources to be able to carryout a plan. This is a very serious step and must not be taken lightly. It is all very well to have an elaborate plan on paper and to think because it all sounds logical that it can actually be done. In many cases a crucial test of practicality is to be sure that one can get the data from the locations specified.

Credibility – here one is expected to be honest and decide whether the plan will result in useful data and outcome. It is unfortunately true that many research projects end up being trivial because of poor identification of data and more importantly the choice of appropriate collection protocols. It is also worth considering the data processing functions as they must also be credible.

Confirmability – this test is about what would happened if the same research was done a second time with the same data – would the researcher end up with the same answer. To put it another way, is the processing method too dependant on an individual and that dependence may lead to bias.

Trustworthiness – here we are concerned that the conduct at all stages is such that one could have confidence that the results are genuine and not manufactured.

3.5 Example Specifications

Here are some sample specifications, they are complete except for the contents list and project plans but they are not meant to be copied without any conscious thought and any obvious attempt to do so will result in specification rejection.

3.5.1 Example Complete Engineering Project Specification

Here is an example engineering specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Detail - jan.smith@port.com for Cohort Started March 2006 (Word Count = 2,414)

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Intention – the customer is SIS and the application is expected to go live by June 12, 2006.

Project Title - An Assessment Marks Processing Application. (See Workbook 6 section 6.13).

Situation Overview

Currently, the core processing is done by staff members dealing with their own assessment marks, typically using Excel. The staff member then forwards his marks sheets, usually in paper form, to the administration office where the marks are collated using Excel to give an overall score for each student. These two marks sheets: individual unit marks and overall student marks are then presented to the Board of Examiners for scrutiny and acceptance. The process ends when a transcript is sent to each student detailing their results for that semester.

Presenting Problem Definition

The actors feel that the root problem is about consistency and accuracy given the sensitivity of the data but coupled with difficulties with storage, retrieval and reporting. (See Workbook 6 section 6.2 and 6.5)

Real-World Target – the desired effects here are that consistency and accuracy are both improved but at a reduced workload. (See Workbook 6 section 6.3)

Application Proposal

Based on the presenting problem there an application is needed that can offer us consistency and accuracy in the processing of assessment marks, both by unit and by overall student performance. The system to be called a mark processing system and it will have the following main functionalities.

Functional Requirements

1. Store name, address, year of study, name of course and unit details of all registered students.
2. Store the assessment patterns for each unit including weights and pass mark.
3. Allow for the entry, updating and deletion of any or all records.
4. Allow for the entry of assessment marks for individual entry or by batch updating via CSV
5. Report on marks for each unit including basic statistics.
6. Report of overall student performance, including basic statistics.
7. Produce student transcripts.
8. Provision for other ad hoc reports at a later date.
9. Secure access to individual results to be available to students through a portal.

Non-Functional and Performance Requirements

1. Store records for at least 6 years.
2. Allow for at least 6 simultaneous users
3. System must be capable of processing all the data and providing the reports within 10 working days. The estimated current volume is 145,000 data entries and 139 reports but this is expected to grow by about 7% per academic session.

Technical Requirements

1. Be developed in MS Access 2003.
2. For use under Windows XP.
3. All processing activities, including reporting, to be carried out using native Access facilities.
4. All processing is to be done using Access VB and no macros are to be used.

Usability

1. Be developed using normal windows formats and standard colours.
2. Fonts use in screen to be no smaller than 9 point and standardised at Ariel Narrow.
3. Assumed screen size to be 19".
4. Report to be printed as appropriate but with fonts never less than 10 point.
5. Data entry load per screen to be as recommended in DEF 981.90.
6. There should be some consideration of access via the portal for the visually impaired.

Ethical Overview

The collection of requirement here does not present any ethical problems. However, when in use the system contains personal and sensitive data and this aspect must be considered in the design

System Architecture

The intended application is essentially a database system with a web link. It will therefore have two interfaces: one a direct link to the database through the Access application and the other through a secure web interface routed through a portal but with only read access.

Strategic IT Value

The proposed application and its functionalities should address the presenting problem very well. In particular controlled data entry, data storage and reporting. This should reduce administration overheads and costs in a cost-effective manner.

Aim

To build an assessment marks processing system using standard MS products in order to ensure consistency and accuracy in the processing of student results. (See Workbook 6 section 6.11 and 6.11.1, Workbook 9 section 9.6.3)

Objectives (See Workbook 6 section 6.10 and 6.10.2 and Workbook 9 section 9.6.3)

1. To produce a detailed, departmentally based, marks processing requirements document.
2. To produce a detailed marks database design using standard documentation protocols.
3. To produce a detailed assessment functional design to include data entry, updating, deletion for marks processing and reporting.
4. To design the secure portal for student use.
5. To produce and evaluation report of the marks application.

Research Design Phase 1 – Requirements Collection Process

This part of the research design is concerned with constructing a reliable primary data collection for later processing into the form of answer expected. In this case the primary data collection is a set of detailed requirements for the marks processing application. The primary data that we need is related to the proposed major functionalities stated earlier and given to us in the form of a proposal. For each of the functionalities it is now necessary to decide. (See Workbook 7 section 7.10)

Location – The requirements can be found at various locations in Portsmouth. In particular

Detailed Functional Requirements: the appropriate targets for this exercise are: SIS office administrators, departmental course leaders, individual academic staff, Heads of Department and the University registry (for regulatory aspects). It may also be useful to make contact with a number of external examiners to ensure that the reporting arrangements are acceptable. In addition there will be various documents such as regulations and marks sheets

Non-Functional and Performance Requirements: the appropriate targets here are the Registry since they set examination and graduation dates as well as define the necessary reports. The office senior administrator also needs to be consulted for staffing and usage issue. During this process there must be detailed discussion with the department and the Registry over security issues as this is a major ethical issue. In addition there will be various documents such as regulations, external examiner reports.

Technical Requirements: the appropriate target here is the departmental technical to establish hardware and software profiles. It may also be necessary to discuss network and security issues with the University central computing department. It may be necessary to see network and PC specifications and various security profiles.

Usability Requirements: the basic design is based in Windows protocols so there are no particular requirements to be gathered. However, because it is possible to implement interfaces in a few ways particular usability requirements will be ascertained by use of a mock-up used with the administration staff. With regard to the Portal there will need to be discussion with the University webmaster over formats and protocols to be used. In addition there will be various documents defining standards and formats.

Collection Protocols – The collection is essential a survey format where each requirement aspect will be discovered by just three formats: (See Workbook 6 section 6.6.1)

Detailed Functional Requirements: expressed as interviews, document analysis (marks sheets and regulations) and some observations. It may also be necessary to use observation to examine any existing Portals.

Non-Functional and Performance Requirements: interviews, document analysis (marks sheets and regulations) and observations.

Technical Requirements: interviews and document analysis (system specifications and profiles)

Usability Requirements: interviews and document analysis (system specifications and profiles). In addition it will be necessary to run some focus groups to look at various interface design option by means of mock-ups.

Requirements Presentation – the requirements data once collected will be presented as interview transcripts, notes and copies of documents. These artefacts will be reviewed and a tabular format used to present the requirements and lodged in the project document appendix.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulates it to get a design for the application. This is in two sections.

Overview – here the vehicle used to present the various requirements in a design format will be UML. The mechanism will be to take the written requirements documents and map them to a suitable diagrams in the form of use cases, class diagrams and where appropriate collaboration or sequence diagrams.

Specific - where necessary a written list will be provided. These will mainly be used to state unambiguously the various non function, technical and usability details.

Logistics and Tools – Required Resources

All the hardware and software are available at the Client's premises and all work including requirement gathering will take place there. The major products needed are: Dream weaver and MS Access and scripting will be done using ASP.

Outline Content List for your Project

See project guidance notes for samples and they can be found in Workbook 9 section 9.3.5 and table 6 but you must also be aware of the marking forms that can be found as Workbooks 11 or 12.

Project Plan

Any clear format may be use but a typical format (but not events) can be found at the end of the Study Project sample specification.

3.5.2 Example Complete Study Project Specification

Here is an example engineering specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Literature Review & Project Specification (Study) – Jan Smith 341387 MSc Computing

Detail - jan.smith@port.com for Cohort Started March 2006 (Word Count = 2653)

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Intention – no customer involved and project results will be used to produce a research paper.

Project Title - Quality Control in Program Development - A Possible Strategy (Workbook 6 section 6.13).

Project Topic Area Overview

There is much interest in Software Quality assurance at present and this is for obvious reasons. Software applications are unlike normal products which wear out and can be tested over time to see where most wear takes place and hence calculate a mean time between failures. By this means failure can be effectively prevented by maintenance. However, in software such wear does not occur although an analogue of this is when other hardware and software components around the software, or the application itself changes and hence problems arise. Typically, we test program code and the more we test the code the more certain we become that it is robust.

Situation Overview

The research is set in The University of Portsmouth with the School of Information Systems. In that context it will focus on the programs produced by first year computing undergraduate students.

Presenting Problem Definition

The problem for developers is focused on knowing when code is robust and ready for release. (See Workbook 6 section 6.2 and 6.5).

Real-World Target

The benefit that would accrue in the real-world if this problem can be resolved or partially resolved is that developers can feel more confident about their product and therefore not risk costly development overruns and compensation claims from clients. (See Workbook 6 section 6.3)

Research Question

How can developers feel sure that software applications are ready for release in order to prevent costly overruns and client disappointment? (See Workbook 6 section 6.7 and 6.9)

Personal Theory

The topic is fraught with difficulty because there is no accepted way to measure program code to see how good it is or even to see if it is correct. Blithe (2002) explains that it is well understood that it is not normally possible to measure, using an interval and ratio scale, in any meaningful way the quality of program code. However, it might be possible to find some means of 'indicating' the quality of the code in the sense that one might be able to pick outliers by taking certain kinds of measurement. It is therefore suggested, that simple measurements of various code properties might be used to pinpoint outliers and hence shorten the testing cycle by transforming the measurement statistically into a pseudo Interval and Ratio scale form which is called Planar Similarity. (See Workbook 6 section 6.5).

Intended Project Outcome

It is expected that the form of the answer arising out of this theory will be a demonstration in the form of a report with graphical evidence that endorses the proposition that Planar Similarity is an appropriate software quality indicator in that outliers can be detected hence assuring the measurement process. (See Workbook 6 section 6.4 and 6.9)

Strategic IT Value

If Planar Similarity is indeed a useful measure of software quality it can be used routinely to examine software in production and give an early indication of quality and that will lead to shorter test cycles and hopefully more reliable software installations and a consequent reduction in cost. In fact Clitheroe (2003,p6) has suggested that detecting all code faults at the initial coding stage might save as much as 23% of development costs. (See example in Workbook 4)

Ethical Overview

There are no current users of the process being developed there would not seem to be any ethical consideration of importance. However, it is necessary to explain to the students supplying the sample programs the purpose of this study and assure them that none of this information will be used for assessment and allow them access to the results if they so wish.

Aim

To report on the efficacy of the Planar Similarity measure using simple metrics as a means of finding outliers in program code and hence reduce coding errors leading to development cost reduction and client approval. (See Workbook 6 section 6.11, 6.11.1 and Workbook 9 section 9.6.3)

Objectives (see Workbook 6 section 6.11 and 6.11.2)

1. To model the software construction process.
2. To report on appropriate simple and synthetic metrics that might be used as indicators of quality in application programming code.
3. To define a process that will extract the defined metrics for any piece of code.
4. To document a suitable statistical process for reducing the metric value set to just two dimensions.
5. To analyse and report on the data, including outliers, and hence derive some general conclusions regarding the utility of the Planar Similarity metric.

Research Design - Research Method

The chosen method will be case studies since I want to see the impact of the measurement process within a defined context and of particular interest in that context is student programmers with differing abilities in writing business application style programs. The case criteria are simple and amount to selecting a sample of students at a set point in their first year of study and a set of matched programming tasks. (See Workbook 7)

Research Design - Phase 1: Primary Data Collection Process

This part of the research design is solely concerned with constructing a reliable primary data collection for later processing into the form of answer expected.

Basic Activity for Generating Data

The basic idea is to compare a new piece of code with an existing piece that is known to be sound and take a series of measurement on each one that might highlight any differences and so indicate an outlier. The idea has some support based on early studies carried out by Sheene (1999) who noted that a reasonable means of indicating quality in program code is to compare similar pieces of code by calculating several metrics for each piece although he did not define how this might be done practically. (See Workbook 6 section 6.8, and 6.9)

Primary Data

This study will define 20 software metrics which will be calculated automatically and for each sample programme. The metrics that form the primary data collection for this research will be such things as: function density, function count, cyclomatic complexity, data associations, decision count, decision density, number of variables, number of function calls, etc. (see Workbook 6 section 6.6)

To set up the case studies three computer program specifications will be drafted with the students working in 'C++'. The specifications will be written so that the defined software application is, in each case, of a different style and progressively more difficult. An expert in 'C++' will produce a set of generics to match the requested programmes – it should be noted that a generic is an outline or skeleton of certain kinds or classes of program.

Location – The sample frame is all first year students on computing courses at Portsmouth University. This is around 350 students and my calculated sample size is 200 students, however, since the data collection process is automatic all 350 students will be used in this study.

Collection Protocols – The collection is essential a survey format where the students will be given the relevant generics and the specifications and asked to write three computer programs of increasing complexity, one in each of three semesters. In this case there is a large data set to be collected and it is not practical to do the collection by hand. In view of this an application will be written that will process each student program so that metrics may be calculated automatically and stored in a suitable electronic file. Students will be requested to deposit their programs on set dates into an online drop box for both marking (not part of this study) and metric calculation. (See Workbook 6 section 6.6.1)

Primary Data Collection Presentation

The sets of primary data will be available in the project document appendix and will be presented in tables where the rows represent the sample programs (one row for each sample) and the 20 columns the metric values.

Research Design - Phase 2: Processing and Presentation

This part of the research plan will take the whole collection of primary data and manipulates it to get the expected outcome form, which was a demonstration that outliers can be detected hence assuring the measurement process. The processing is in three steps: manipulate the raw primary data, presented the processed data in graphical form and extract from the graphs features by manual inspection.

Design of Pre-Processing for Primary Data Collection (Workbook 6 section 6.6.3)

The metric data sets will be read directly from the files produced in phase 1 and then statistically processed to define a similarity measure for each program using principal component analysis and multidimensional scaling. The outcome of this processing will be pairs of values, one pair for each sample program, suitable for plotting in two dimensions.

Design for Results Presentation

The pair of values from the first processing round will be plotted in two dimensions, together with the results for the generics producing three graphs one for each program specification.

Design for Generating the Intended Project Outcome

Once the graphs are available it is then a simple matter to look for outliers in particular and attempt to explain their distance and orientation from the generic and other programs in the class. The contention is that similar programs will cluster together and ones that are different (even though the specification was the same) will show up as outliers and can be identified and examined to see why that difference occurred. It is hoped that the results will be similar for all three program in that data set and hence demonstrate that complexity is independent from planar similarity.

The final step is to use the identified outliers to go back to the actual program code to explain why the code produced the outlier. In this way it will be possible to get an indication of why a given program is deficient. This final processing step allows me to generate my report on Planar Similarity that contains my overall findings and evidence on its utility.

Logistics and Tools – Resources Required

All the hardware and software are available at the University. Since the data collection process is automatic the use of staff resources is minimal.

Outline Content List for your Project

See project guidance notes in Workbook 9 section 9.3.5 table 6 but you must also be aware of the marking forms that can be found as Workbooks 11 or 12.

4. WORKBOOK 4 – LITERATURE REVIEW & STRATEGIC IT VALUE NOTES/EXAMPLES

This is a sample of what is expected in assessment 1a, however, it only shows two elements: the strategic business IT statement and the short Literature Review. Try to keep in mind that this is just ONE example and do not try to copy it blindly or try to fit it into what you want to do.

Strategic IT Value

This work was based on trying to resolve or partly resolve the problem of low quality code leading to the need for costly re-work at later stages in the development cycle. The importance strategically of this work is that the outcome: a definition of new software metric will imply that it is possible to identify poor application code and this can be done at an early stage in the software development life cycle. The importance of this is that corrective action can be taken early in the development cycle and as a consequence costly re-work late in the cycle can be avoided or reduced. A secondary or added value element is that the results will allow the identification of good programming standards and this in itself will also lead to improvement and strategic advantage on all products delivered.

Tutor Comment

The key element here is that one relates the expected outcome or form of answer to its use in resolving the problem theme that was the basis of the project, and hence demonstrate a strategic business IT value. Failure to create a clear argument based on the problem theme and outcome leading to a strategic business IT value will mean loss of marks.

Literature Review (See Workbook 5 but note section 5.6 in particular)

Hiskett in his 1987 seminal paper on metrics defined several apparently useful metrics, the best known of which are 'program vocabulary' and 'program length' which are essentially metrics that count operators and operands and their usage in a given piece of code. Hiskett's metrics are easy to calculate but he was unable to show any strong correlation between his measures and program quality as defined by experts in the field. Similarly, Rogers and Hamerstein tried to use Hiskett's metrics as predictors of MTBF in accounting software but the results were inconclusive and no link could be found between the metrics and the type of software (functionality), accounting in this case, and the metric used.

Garlick, Sheene and Southwood (1999, p450) attempted a new approach that involved the notion of similarity, which they called planar similarity – that is two programs could be defined as similar because: they are written in the same language or they perform similar functions or they were written to the same standards or they are written to the same specification or they were written by the same team or finally they perform the same function. Their work is aptly summed up in the opening paragraph of their paper:

"The nature of any true measurement is easy repeatability and this implies that the style of measurements form a suitable metric space. This means that we need to define the nature of the similarity before we define a measure. In principle this is simple since it is easy to name the similarities but in practice it has been difficult to articulate a precise definition."

The similarities described above deserve further explanation but here only two of them in combination are used: similar language and similar or same specification. Similar language is easy to understand but at first glance it would seem that if two different programs are written to the same specification they are bound to be the same. However, after a little thought, it is obvious that if two different people write two different programs to the same specification the programs are certain to be different in many respects. It follows that that the basic, though loose, hypothesis is that if planar similarity can detect a similarity (alternatively difference) in these programs - written to the same specification but by different people - it might be possible to use planar similarity to detect differences between two or more programs against any defined mode of similarity. Conversely, if it cannot be shown that a similarity exists between two or more programs written to the same specification then there is no hope whatever of showing any other kind of similarity with this metric.

Two final points need to be considered: what exactly is meant by software quality and why would a similarity measure be a good indicator of quality? To answer the first question we have only to refer to Kitchenham's 1998 paper where she defined five kinds of quality, briefly:

Transcendent View – quality is a kind of innate excellence, something felt rather than seen.

Product Based View - quality is related to the content/attributes of the product.

User View – quality is seen as equivalent to fitness for purpose.

Manufacturing Based View - quality is equated with conformance to specifications.

Value Based View - provide product at an acceptable price and conformance to a specification.

In this study the transcendent view was the one chosen as the basis of the definition of quality. The meaning of this view is defined by experts in the field – that is, can an expert in, say, Java programming make a judgement as to whether a given piece of code is good or bad – well, here it is argued that such an expert can and does such tasks routinely. Curiously there is very little literature on this idea of expert opinion within the software community but Gavin as early as 1978 touched on the subject. However, it is a reasonable conjecture and it will be used in this study – interestingly, if it can be shown that planar similarity can detect similarity (or equivalently differences) then it would also support the conjecture that experts can judge software quality.

Finally, the study will rely on the ability of experts to judge quality in software. This judgement is exemplified in the production of exemplar or generic programs. Garlick (2003, p98) has written extensively on this subject and the work is well known and will not be fully reviewed here. However, it is possible to define classes of program modules - validation, input, calculation, reporting and so on – it follows, that using the idea of similarity it is useful to create a standard or *generic* program or module for each class. Such a program can then act as a base line for all planar distances related to its application class and hence be a measure of similarity (or difference).

Using Garlick's idea we can let experts define our generic and then use that to compare with other programs – if we declare a difference then in simple terms we need to look at that program because it might be of poor quality and conversely if we declare no difference then we can fairly conclude that the program is sound.

Tutor Comment

The literature review is supposed to be a student's own work. As such it is a discourse that outlines the major areas of a topic area but amounts to an essay which is the student's alone. In practice this means that students must read deeply into the subject and then weave what is read into what the student already knows or believes in order to create a useful summary of the topic that will form a strong base for carrying out the actual primary data research - this implies that you 'master' the subject area and become expert in it.

It follows from the above that if all you do is copy or paraphrase from various sources without any significant comment or analysis on your part then it amounts to plagiarism and is worthless.

One final point is that when you write up your review in your final project document you should use various sub-headings and other formatting elements to structure the section to make it readable and meaningful.

5. WORKBOOK 5. LITERATURE REVIEW

The main function of this review is to ensure that one's mind is prepared with all the specific problem area knowledge that it needs to carry out the project and its primary research. In practice this implies the rather difficult task of integrating different ideas, theories and experiences into a thematic, informative, complete and clear discourse on your chosen subject area.

Preparation of the mind is done through adding your critical evaluative comment on what you find in the available literature and such critical reviews are typically hard work and not about downloading a few articles from the internet. The key characteristic of the greatest thinkers in history was absolute and unswerving honesty in all their thinking and that principle has never changed. They used their intellect and reasoning abilities to the full. They were honest no matter what the subject be it religious, political, business or academic. These men would not accept dogma from religion, politics or academic sources without subjecting it to serious critical questioning and of course this often meant great suffering for them.

5.1 Plagiarism

The KEY is honesty – without that your work is worthless – you may be able to fool some people but as Shakespeare said “This above all: to thine own self be true, and it must follow, as the night the day, Thou canst not then be false to any man. So when you plagiarize I may not know, the University may not know but YOU will always know that you obtained something falsely.

Plagiarism means passing off other people's ideas as your own. In academic life, it is one of the worst things that anyone can be accused of, as it is a form of stealing or cheating. It is fully expected that students will carry out research prior to completing a piece of work. This may include the use of books, journal articles, reports, manuals, notes and so on as source material. The material may be public, restricted to a closed set of people or with a security classification), or privately communicated. The principles are the same whether the material is on paper or in an electronic format. When you refer to an idea in a piece of your own work, it falls into one of several categories:

Common knowledge - many people know it and the information does not belong to anyone person but it cannot normally be deduced by you it has to be learned. It is probably talked about in several sources: the world is round, computers contain both processors and memory, OO is routinely used in software construction and so on. If you are sure that it is common knowledge, you do not need to cite a source. Be careful, authors will often write down in their own work things that are common knowledge so quoting them in that instance amounts to saying that a bit of what is common knowledge actually belongs to that author and that of course is an absurdity.

Obvious – many people know it and the information does not belong to anyone person but it can be deduced. It is probably talked about in several sources: companies tend to grow as time goes on, when the sun goes down it gets dark and so on. If you are sure that it is obvious you do not need to cite a source. Be careful, authors will often write down the obvious in their own work so quoting them in that instance amounts to saying that what is obvious to every one actually belongs to that author and that of course is an absurdity.

Published – this refers to an idea that found in a specific source or sources which is not common knowledge nor obvious but is nevertheless useful – in these cases you must always cite the source or sources of such an idea.

Original – you may include freely original ideas of your own. However, be aware that if the reader sees an idea that is not cited and is not common knowledge nor obvious, then they are entitled to believe that either it is a new idea published by you or you have plagiarised it.

5.1.1 Identifying Plagiarism

Plagiarism does not occur only when you copy words verbatim. Plagiarism is about ideas, and even if you express the idea in your own words, you may still be guilty of it if you do not credit the source. However, expressing an idea in your own words might often be good scholarship. The difficulty is that anyone can copy and paste a phrase, sentence or paragraph and cite its source. This is technically not plagiarism, but it's often very poor scholarship since it is obvious that such an activity tells us nothing about the learning, if any that has occurred

Scholarship is about showing your understanding and criticism of ideas. Simply copying, paraphrasing or summarising can only show understanding only to a limited extent. You need to "add value", that is make your own contribution to knowledge, to what you've read and you can usually only do this by expressing an published ideas in your own words and mingling them with your own thoughts and ideas.

5.1.2 Common Critical Devices

The essence then is to infuse your work with your own thoughts and ideas and let these mingle with what it is you have found in the literature. The most common forms of this are:

Interpretation - explaining and expanding on what you have found.

Criticism – discussing in order to judge whether the ideas are good or bad.

Decomposition or Analysis – to tease out the constituent parts of an idea.

Synthesis – by means of discussion and explanation link separate ideas together.

Selectivity - showing which ideas to include and which to discard.

Abstraction - taking an overview or defining a model or framework, usually by looking at examples.

5.1.3 Common Literature Tools

The following are the most common means of incorporating, in a scholarly fashion, the work of others into your own written work (a fuller discussion of these tools may be found in the notes).

Copy – use the exact words using quotation marks. A good rule is that each quote holds a single main idea, which you want to use and then you must introduce it and then follow it up with discussion.

Paraphrase – expressing something that you have found in the literature in your own words - the intention being to simplify, explain, or interpret a complicated idea. But take care there is a very fine line between simplifying, explaining and translating something and just being lazy.

Summarise – producing a précis or abridgment of a part of the source we have found. Essentially one is trying to capture the main points in an argument.

Analyse – the purpose here is to offer a detailed examination of some whole by scrutiny of its parts.

Synthesise – here the idea is to take parts and put them together into a new whole for some purpose.

You might find it useful to remember: copy in order to discuss, paraphrase to simplify, explain or interpret, summarise to capture the main points, analyse to understand and synthesise to build something new.

5.1.4 University Review Assessment

When the University looks at your Literature Review it will be trying to decide if you are committed and prepared for the topic and working at Master's level. If your work is poor in terms of structure, content and form you will find yourself failing. This is NOT necessary so long as you put in the work and ensure you understand how to use citations and the literature. I want to encourage you to do good work - it will ensure that you pass well and it makes your work a pleasure for the Examiners to read.

5.2 Review Content

The review is about your topic area and about you becoming sufficiently expert in it to deal with the problem that you will have uncovered. The intention is for you to offer a discourse that is focused, relevant, authored, measured, evaluative and expressed as a dialogue. (Notice the acronym FRAMED)

Focused – this means that your whole effort is focused on the topic area and the particular aspect of it that you are pursuing. So do not be tempted to add in other things just because they might be useful, interesting, and novel or you just have nothing else to say.

Relevant – any topic area aspect will itself normally represent a large body of knowledge and so one needs to continually ask if a particular element in the knowledge domain is relevant to your particular study.

Authored - any literature review is to be written by its author. This sounds obvious but it is all too easy to fill up a review with cited quotations, paraphrases, summaries and so on so that the 'hand' of the review author is not evident anywhere in the work. When this happens it is not an evaluative review at all but simple plagiarism. The author's 'hand' must guide and direct the review in an evaluative fashion so that the review is a message from the review author and not a recitation of what has been found elsewhere.

Typically this is done by using ones own skills and knowledge to introduce, comment, add to, modify and extrapolate from various primary sources available.

Measured – this is a matter of selecting and using the focused and relevant materials that you have found. Unfortunately, It is all too easy to pack in information in excruciatingly precise detail and so end up with a laboured entry that treats your readers as if they where completely ignorant of the subject area. So here one needs to just say honestly “is the entry a measured response to my and my readers, information needs”.

Evaluatory – authors sifts through the primary sources looking for materials to use. The essence of this sifting is an evaluatory outlook based on an awareness of your problem theme and your topic area. Care is needed because this process is not about searching for materials that you agree with or like in some way. Instead it is a contextualised response (what do you already know) and that may mean you find materials that are new to you, materials that make you change your own knowledge base and often materials that completely replaces what you thought was solid.

Dialogue – a review is a form of argument because good ones are based on a strong theme and in them one is trying to explain to, and convince your readers about something and so it is best if you think of it as a kind of dialogue in which you vicariously challenge them about your review theme and content.

5.3 What goes into a Literature Review

It will depend to a large extent what it is you are working on and what you want to say but the following list give some common ideas of content.

Challenge – this is two way: what you read challenges you and you challenge what you read for validity and applicability and so one might find new ideas or change our perspective.

Consolidation – reading widely consolidates your own knowledge base in that it can confirm or show any gaps in your knowledge.

Exploration - implies searching for new ideas, theories, concepts, rules and so on.

Self Check - affirm what we know for currency and accuracy

Support - the reading might support or be in opposition of ones views

5.4 Integrity and Evidence

This heading sums up research - integrity because it must be your own work and evidence because you MUST be able to show that your results have value. There are basically 4 strands to good work as follows

Dogma – this simply means things you have to take at face value. Most often they are things that are not open to reason in the sense that one is not allowed to question them and in some countries you can find yourself in serious trouble if you do. The problem with dogma is that by definition there is no logical support for it. Just to use a simple example, some faiths require you to have a beard or not eat pork as a matter of dogma – in such cases we usually cannot logically deduce that this is a right or wrong thing. It may of course be simpler than that since we all invent our own dogmas from time to time – for example it may be very simple such as ‘I will never buy a Ford car’.

We all accept dogma but that really is not the issue – the issue is that we should not accept it without some critical thought. There is at least one rational way of exercising critical thought on dogmatic issues and that is asking is the outcome of actions based on it good, bad, neutral or at least does not harm anyone. The trouble however, is that dogma sticks to us like super-glue and we will often go to great lengths to defend it and almost always this is done by sophistry (worthless arguments) and of course the notion of what is good or bad is not easy to define.

Reason – this is the ability to be logical and reason about what it is you are reading or writing. That is you are encouraged to ask questions and seek for a deeper understanding. This may imply that you accept new information, modify what you already know or reject something as no longer valuable.

Honesty – here we are talking about not taking things at face value and being honest with yourself about what you are reading or writing and asking does it all make sense and is it coherent with what I already know.

Motive – this aspect is about your reasons for wanting to read or write something. Now such motives can be high minded or they may be base. One must therefore always guard against tendentiousness (the author simply wants to convince a reader of something and may use any means to do it) in ones own writing and be watchful for it in the writing of other.

5.5 Literature Sources

The available literature is classified broadly speaking into the two kinds described below and ideally we only want to use primary sources.

Primary Sources – that is the first published documents. One can be really pedantic and say the real primary sources are the author's manuscript or autograph but these days we are satisfied with published sources. It will however, often be difficult to establish that something is indeed a primary source.

Secondary Sources – in almost every document you see, there will be elements attributed to other authors – these are then secondary sources.

Be careful not to confuse the above definition with those for primary and secondary data. When we talk of primary sources we are obviously referring to something that is published and exists whereas with primary data it will not exist until a researchers defined, locates and collects it.

5.6 Basic Writing Rules

For Study projects a full literature review will be needed but for Engineering projects the requirements document forms part of the Literature Review. However, even in Engineering it is necessary to write a short review just to form a technical backdrop to your project. It may help you to remember there are two cardinal rules when writing – they are simple:

Respect – always have a deep respect for ones readers and make it easy for them to understand what you are saying.

Need - only quote, paraphrase or summarize when it clearly adds to what one is saying. The key task is to formulate ones own ideas, in your own words but one does this by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

5.7 Literature Assessment

When assessing this element the University will look at how YOU use the sources in what you write and at the range of sources that you used. If either is judged deficient your work may not be accepted as the view taken will be that you are not prepared for work at this level and on this topic. It is expected that all your sources will be mostly primary ones. If there is some reason why this is not possible it must be discussed with the Research Methods tutor or your project supervisor.

5.7.1 Literature Review Structure

All the following steps are iterative and you must expect to go backwards and forwards many times before you get a review with which you are happy.

List – Make a list of all the various topic strands that you need to know about. It may help you to think about strands such as: organisational, administrative, functional, social, technological, cultural, ethical and so on or some other structure best suited to you topic. Remember, this is not about writing down everything you know it's about giving your readers a focused discourse on your chosen topic area

Arrange – Use your prepared list above and put the topics into a logical and progressive order.

Theme – Decide on a theme that will link all the various topic strands together.

Structure and Content – Now use your themed list of topics and structure what you write using headings, subheading, paragraphs, bullets, tables, diagrams and so on.

Reading/Writing with the Intellect - This is normally thought of as a four stage process that applies equally to what is written (because it is going to be read by someone).

Understanding – this is simply taken to mean that we understand the words used.

Interpretation – are able to find meaning in the words used.

Evaluation – we ask does the meaning have any value – in essence we ask is it true or false.

Contextualization – this implies that everything we read is coloured by what we already know. This idea is taken much further in the idea of hermeneutics (see the notes).

Usage – the literature that you find and evaluate can be used to supplement your own work and demonstrate your mastery of the topic area. This does not mean that you quote, paraphrase or summarise everything you see. As a rule of thumb: only quote, paraphrase or summarise when it is necessary and it is not common knowledge and it is not an obvious observation.

Argument - Finally, keep in mind that when writing you are dealing with a form or argument where you are trying to persuade your reader about some point or other and that should only be attempted when you are knowledgeable, the argument is essential and you have a deep respect for your readers.

5.7.2 Literature Review Construction

Here is a plan that you can use to construct your own review. It is not infallible and will require conscious effort from you and it must be based on a thorough evaluation of the literature.

Step 1. Purpose - the purpose is to fully prepare your mind with all that you need to know about the topic area and the particular element of it that you are focusing on. The idea is that what you write shows your mastery of the topic and in fact you have become an authority on the topic area. So a review is not a long list of quotes, paraphrases and summaries, it is an evaluatory discourse. That is, readers will want to know what YOU have to say based around what you have uncovered in the literature - so readers must see what you have found and see what you have to say about it.

Step 2. Topic and Aspect - Make sure you are clear about your topic area and which particular aspect of it you need to explore and understand in order to be able to effectively carry out your planned research.

Step 3. Select a Theme - Use your project problem definition, target and outcome to guide you in selecting a theme that will connect all the various elements of your review together making it a lucid and progressive discourse. (Don't be afraid to alter the theme as you go along if that becomes necessary)

Step 4. Your own Views - Try to make a list of your own views, ideas and knowledge. Remember, the review is an evaluation of what you find not a recitation of it. If all you do is tell us what you have found you may not even pass because almost anyone can write a review on any subject if all that is required is to more or less recite what has been found. So you must structure the review around your theme and your own ideas and thoughts.

Step 5. Make a Review Content list - Based around your theme make an outline list of things to include and then arrange the list into an order that will take you progressively through the topic area aspects. Commonly it is found that it is useful to start as follows.

5a. Basic definitions and terms that need to be clear for the core topic area. (Be careful to note any abbreviations)

5b. Map out several important areas or problem space dimensions. Now it is impossible to be general here so for example if I were looking at mobile devices and their use in business I might map out the following elements: value, attitude, use, limitations, practice cost, ease of use, learning curve, effectiveness and so on. Please be careful here to look for significant things not just drag in anything and everything. Once you have made this list you may add to it, modify it or discard from it as you go along.

5c. Work out how you want to end the review - often this just sums up your point of view but you may have other ideas

5d. You may like to include some statistics if that is relevant. But don't let this run away with you and so the review just becomes some sort of justification based on statistics. Remember, statistics almost never tell us anything about the topic itself and only tell us things related to the relative importance of certain things we have identified.

Step 6. Literature Searching - Armed with your theme and list of elements now start your search for suitable material but be very careful to record the exact details of where everything may be found and checked. The search may start with the Internet or a special tool like Google Scholar but must move on to respected publications.

Step 7. Structure - The step is to structure what you have found and what you want to say about it so we get a coherent and lucid discourse on your chosen subject area. This is not a trivial matter and you must expect to go over it many, many times before it is really an example of your very best work.

5.7.3 Literature Review Traps and Pitfalls

Most of the things listed below are regarded as due to simple laziness and so are unforgivable in a Master's student or indeed any research student and if you are guilty of them then expect severe punishment in terms of loss of marks or failure overall.

Not a justification - A literature review is NOT a justification for your research idea or problem definition. So filling the review up with various statistics will never be regarded as explaining to the reader the topic area and your evaluation of it.

Statistics - Filing up the review with statistics carries no real value in convincing the markers that you are master of that topic area.

Poor Structure - where the review is little more than a few drafts notes obviously written without much thought. To communicate you must impose some structure on what you write else the readers will not be able to see any progression in your thought or in the topic.

Filling up the review with citations - one after the other with no student input. It is correct and desirable to tell your readers what you have uncovered but unless you make comments and add your own views on what is found the work will be regarded as worthless.

Common knowledge and Obvious - Quoting or paraphrasing material that is either obvious or common knowledge implies that you have not looked at the sources beyond the first page or forward. Here is an example from a project document. "Poston (2000) stated that organisation expected ERP systems to deliver improved performance". This is worthless as it is obvious that they would want this and to say it make no valuable point at all - its no good trying to say things like this as if Poston was enunciating some law of the Universe or a point of huge importance on some new and valuable angle related to ERP - no he is just stating the obvious.

Bad citations style - It is very common unfortunately to see the citation form (Briggs, 2000) placed at the end of a sentence or paragraph. When we see this it can ONLY mean that all you have done is paraphrased, summarised or copied that section. This practice is more or less plagiarism and is representative of a very lazy attitude that assumes that just expressing something in your own words is a valuable contribution - its is not because YOU are saying nothing and what you are supplying is not really your own work at all.

Activity Definition - Some students use the Literature Review to tell us what they are going to do in the research. This will result in a zero mark as what is to be done is covered in the Research Design so repeating it here is valueless. This practice is a certain sign of laziness.

5.7.4 Reference and Bibliography

References are to primary sources that you use in the text of your written work. A bibliography is a list of sources you have identified as useful, including references, but not necessarily used. The University will look very carefully at any references to see if you are prepared for study at Master's level in your chosen topic area. Overall, the expectation is that you will list at least 10 sources. For each source you must consider its:

Currency – looks at publication date and be aware of changes in technology.

Completeness – Make sure you are looking at the final version not some draft or abstract.

Uniqueness – is the source a primary one

Coverage – Use your list of sub-topics to ensure that you cover all the areas required so that you are fully prepared. But make sure that you are not including multiple texts with essentially the same content.

Range – Make sure you have a good range of authors.

Authority – ask is the text authoritative. This can be done by considering the author, publisher, writing style and currency. It is also possible to use citation indexes to see how often the source has been used.

Accuracy – Is the information correct? If you cannot be sure then you must not use it.

Relevance – Make sure that your sources are relevant to your project topic.

Usage - The basic usage strategy is:

Find – Relevant texts using a library index, the internet, online book stores and so on.

Evaluate – Once you find a possible source you must evaluate it for content and relevance.

Contextualise – that is fit this new source into your personal knowledge base.

Cite – If you use a source it must be listed in your reference section and cited in the text correctly.

Discuss – You may include something from a source in your work as a copy (quote), paraphrase or summary but in all cases you must introduce it, comment on it at cite its source.

5.7.5 Evaluating Internet Resources

When using internet resources it pays to be careful and always sceptical because of the following factors:

Anarchy - anyone can publish just about anything on the Internet

Validation - authors do not always have their materials checked by an authoritative third party

Tendentious – when the author wants to convince you of something use any means to do it.

Honesty - authors may not always be what they seem and may assume personas, lie or make false claims

Consider – the motives of those who publishing on the Internet

Trust - in research trust nothing until you have good cause to do so. This is the opposite of what we do in our daily lives in that we tend to trust until we have reason not to

Context – be aware of the context of what you find. For example is it a University site, is it a manufacturer and so on.

Accuracy – this simply mean is the information correct. You need to be aware that information might be validly collected but still be quite inaccurate.

Validity – this simply means that we ask is this a valid source in the sense that it was constructed in a reliable manner. Any lack of information on proof readers, editors and publishers means that mistakes are more prevalent than in print and therefore increased scope for innocent error and for outright deception.

Authority – this means was the author competent to create this material. For example any one could have an interest in say Emotional Intelligence and quite easily create an internet article on that subject but it would not have the same authority as that of a University professor who has spent years researching the topic.

Uniqueness – here we are asking is this an original work (a primary source)

Completeness – this may simply be described as asking if the work is the final and finished version. You need to be very careful here else you might find your self using the material from the earlier part of the work which in fact is augmented later in the work.

Coverage – this means what is the scope and scale of the source. Now this does not mean that a source will cover everything on a given topic but it should be clear as to what it is covering.

5.8 Citation Examples

The following set of examples is intended to show some poor use of citations and also some sound ones. These examples should be studied with care by students so that they may avoid inadvertently fall into the trap of using poor scholarly practices. The quotes are from a range of sources and topics and in your study of them you need to concentrate on the form. Now assume all the following were all written by the Research Methods tutor so the comments will be offered in the first person and he is talking to you

These are just simple examples and they do not imply you must use italic or indenting as that is only used here to show clearly the pieces of work being looked at.

Example 1.

Lyau & Pucel (1995) found a link between training and productivity for their sample of Taiwanese car part manufacturers. Bartel (1994) found that training is a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors. Bishop (1994) and Barron, Black & Lowenstein (1989) both found that training increases management estimates of productivity.

This is poor because I only told you what the cited authors said. I did not introduce the author's words, nor discuss them and it's almost impossible for you to see what point I am making other than the obvious one that productivity and training may be linked – in effect it is not my work at all and there certainly is no sense of evaluation here.

Example 2

It has been found that because Arabic words were written by copyists who did not use vowels that over time the meaning of some words has been lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. One way to deal with this is to use assonance and in this paper that approach will be taken (Noldeke 2003, p45).

The problem is that it looks as if I attributed the entire paragraph to Noldeke. So you can have no idea which part of the paragraph was my own thought or maybe none of it was. This is bad practice and some tutors even regard it as blatant plagiarism. The fact is that tutors when they see this form in will automatically assume that all the student has done is paraphrase what he has found and none of it in effect is representative of any student thought and will mark the work down because of it

You can use the bracketed form if you just want what amounts to passing reference to a source as in the following example.

In two recent works (Harding 1986a, p.80; 1986b, p.138) it has been suggested that ...

Example 3

St. Clair-Tisdall (1994, p45) said in his seminal paper on Organisation Synergy that "change in organisations is an inevitable consequence of growth" – this is an interesting observation and implies continuous IT progression and updating. Knowing this we can support Briggs (1999, p23) who said that OO is now routinely used in the computing industry.

This is poor because the first statement by St. Clair-Tisdal is clearly obvious and that by Briggs is common knowledge. Also it is not entirely clear that the second sentence leads logically from the first one. The point is that using citations here was unnecessary and therefore worthless.

Example 4 - Suppose you come across the following in a book by Noldeke. But the bit that interests you is by Frederickson – how will you set about properly using and referencing the Fredricksons quote?

Tools are needed if we are to measure software quality in a meaningful way. The idea of quality, as we know, is intangible since many views are possible. It follows that we must define some terms in order to measure quality. It is useful to note what Fredrickson said: "Definitions of what quantities we need to measure in order to assess software quality are at present arbitrary since as far as we know they have no connection with functionality".

This does not mean that they lack a rationale, but simply that professionals disagree on the definitions themselves and so it follows that

In this case the correct way is to find the Frederickson book and use that because it is the primary source. Quoting from secondary sources will only be tolerated in proven cases where the primary source cannot be found or for other reasons is inaccessible and it must be done in the correct manner as shown in Workbook 8 for secondary sources.

Example 5 – Can you work out what the following extract from a piece of student work is saying – if you can please tell us in simple words

It is argued that tacitness, complexity, and specificity in a company's skills and resources can generate causal ambiguity in competency-based advantage, and thus raise barriers to imitation (Fahey, 1989). This is to rise a company's distinctive strategic positioning so as to possess some form of sustainable competitive advantage.

The sentences is obviously copied as it is very, very unlikely that any student would write with such academic complexity and obscurity – lines like this are not designed to communicate they are designed to impress the reader not further his understanding. What it in fact it is saying is that some skills are very difficult to duplicate and this may mean that growth may be restricted.

Example 6 – Here is a good example and in this case I paraphrase the idea rather than use quotes. Notice how I: introduce the idea, state the idea and discuss the idea and so I weave into quotations, paraphrases, summaries or whatever my own words and thoughts and evaluations.

There has been a long standing problems with some early Arabic manuscripts in that many words have become obscure and even in context they are still unclear. Bigly and Ahmed (1978, p340) and others have shown conclusively that because Arabic words were often written by copyists who did not use vowel, over time the meaning of some words became lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. It has been usefully suggested by Noldeke (2003,p87) that one way to deal with this is to use "assonance analysis" to study word endings and in this paper that approach will be taken and in particular we will look at some early Arabic poems by Averroes.

5.9 Literature Reviewing Cautions

Writing a literature review is a difficult and time consuming task if it is to be done well and there are no short cuts to sound scholarly work so here are some final pointers.

Laziness - It is very common to see students write down things in a literature review as they occur to them. This practice might be fine for notes but it is obvious that the way thoughts pop into ones mind or information is discovered is most often anything but logical or structured.

Structure – to communicate in writing the work must have an effective structure that is well planned and allows the theme to develop to it natural conclusion.

Pretence - some students try to be scholarly and pack their work with quotations and paraphrases – this then become not an evaluative review of what was found but a recitation of it instead.

Non Review - some students just write down what they know without any references to the literature – this will always lose you marks as no one will believe that you obtained that information by your own brainpower without any outside assistance.

Experience – students often claim that what they write is all down to experiences but again no one will accept that. They way you use experience is in your evaluation of the sources, comments on them and building up your own arguments.

Inclusion – Preparation of the mind for your topic area does not mean you write down everything you know that might be relevant. What it does mean is being focused on your topic area and becoming expert in that. For example, an Engineering project where the literature review contains page after page devoted to telling the reader about every conceivable life cycle is hopeless and in such cases there is almost no thought over what is written and so it is worthless. Similarly, if a study project was looking at eCommerce as a way of selling drugs then page after page telling us about various drugs, treatments and prescribing practices is worthless in the context of just selling drugs. It's not volume is wanted but considered content.

6. WORKBOOK 6 – MAJOR PROJECT ELEMENTS

This workbook is intended to help students formulate clear project elements but here that what is said here is a mechanical process and it is your responsibility to make sure that what is written down makes sense.

6.1 Scope and Scale

Scope and scale are meant to be considered carefully otherwise a project which is out of control and way beyond your capabilities in the time available may occur. Alternatively, the scope and scale may be set so that the problem becomes trivial and the idea is rejected. So please take note of what these terms mean as far as this course is concerned.

Scope – this means something like selection or choice. So for example, if I were looking at training in desk-top packages I might select just Excel or I might select Excel and Access and so on to focus on. The point is I set my scope by being selective.

Scale – the means something like number or extent. So for example if I set my scope as looking at Excel I now need to set the number of users I will include in my study.

Scope and scale are two dimensions that set a frame around your work to bring it into sharp focus and exclude everything else. You need to put limits on both these dimensions but it is most important is to be clear about scope – that is, what exactly to include in your study, normally, just include ONE significant thing.

6.2 Presenting Problem

In any project it is usual to choose an area of knowledge and practice to be its topical focus. For example, one might choose modern usability issues, automated network management, digital paper and so on. Once one has a topic area like this it is necessary to choose a problem theme within it to be a sharp focus for a primary data research effort. It is best if one problem theme is chosen and its resolution or partial resolution would be of strategic business IT significance. In general, it is not all that easy to give a simple and all embracing definition of the notion of problem but the following has proved to be useful.

A problem or issue is something that is a matter of concern or debate within the topic area and whose resolution might bring benefits. (Checkland 2003)

In practice this means a problem is an object not an activity. For example, stating the problem as “how to ride a bicycle” is incorrect since this is not the problem it’s a question about the problem - the problem is “riding a bicycle”.

Another difficulty is that students often write down the problem in such a way that it is an answer or solution to the problem. So for example, if one writes a problem statement as “lack of training” then implicitly that is a solution as well. When this happens it is almost certain that the writer is not thinking about the problem at all but is obsessed with a particular solution. In this particular case the real problem might have been “errors in data entry” and one of many possible solutions is training.

6.2.1 Defining the Problem

It is always quite a good idea to construct one's own definition of the problem and to do it in as few words as possible. Notice, that it is your own definition not one you might look up in a book or on the internet (though you might start with that) because there is often little learning value in just copying a definition as far as deepening your own understanding is concerned.

Remember, that any definition one constructs will not be absolute and universally accepted by everyone - but in research this is not a problem as long as the researcher makes it clear what particular definition is being taken. Do not take this process too far and end up with either over-complicated or trivial definitions - they must be thoughtful and comprehensive. So it is recommended you start by thinking about four things where the acronym CAPE is used:

Characteristics – observable features or facets of the problem idea,

Associations – every problem will have links to other situation elements,

Perspective – when a problem is encountered it will always be from a certain perspective

Effects – say what effects ensue in the real world if the problem is not resolved.

6.2.2 Defining the Problem - Example

Let us suppose that a student has identified the problem theme as Phishing. Naturally, the student will be concerned that this is a good idea and would like confirmation of that before expending time on it. One can

ask the course tutor, but he/she is not expert in everything so at best one would only get an opinion as a response so how should a researcher proceed. So for Phishing a researcher might note the following:

Characteristics: illegal, intrusive, upsetting, preys on those who trust their fellow man, etc

Associations: email, chat, file sharing, etc.

Perspective: management (but try to look at it from several perspectives as well)

Effects: destroys confidences in the system, may lead to personal or company losses etc

Normally, it takes quite a few attempts before a definition that is lucid and comprehensive is obtained. Remember, the definition must also be useful within your research study – that is, it's no good having a well formed definition that does not offer a sound basis for a research effort.

Now here is a first attempt

In the modern world email is a technology that almost everyone uses whether in the home, at work, on the move and indeed it seems to follow one around. Typically, email is a simple one-to-one message passing technology but it is now offered with enhancements that include voice, video, chat, file passing, file sharing where suppliers are attempting to present a complete communication environments. With such a technology come problems and one such problem is identity theft and one way of getting this is known as Phishing. In its simple form an unknown, but apparently authentic, source asks for personal details and then uses them for fraudulent purposes. The problem is identity theft using email systems where a message poses as a legitimate requestor in order to fool the recipient into thinking it is legitimate request. The problem in computer system is known as Phishing.

Here is a final attempt (but most often there are several intermediate attempts)

Phishing is identity theft using email where a personal message seeks confidential or private information from its recipient whilst posing as legitimate request. The intention therefore is to fool the recipient of the message into releasing information which can subsequently be used for fraudulent purposes.

6.2.3 Cautions on Problem Definition

The acronym CAPE is just an aid to formulating a definition so one should not worry whether something is a characteristic or an effect - that does not matter very much because the whole idea is to uncover problem aspects and expand one's understanding of the problem theme.

As a very rough guide one often finds that the final definition must come down to about a third of what we start with. In most cases if one is familiar with the subject it is possible to create a good definition in about 1 to 2 hours and then if necessary update it as your project progresses as it is almost certain that there are elements that have been missed or imperfectly understood.

6.2.4 Problem Size

It is hard to measure the "size" of a problem because there is no scale on which to gauge it. But one can look at two aspects to get some idea.

Current Effects – think about the effects of the existing problem and try to assess their seriousness in terms of the context in which it is set. In simple terms just ask "is it worth solving".

Form of Answer – perhaps a better guide is to think about the form of answer and see how extensive, important and how hard it is to get. For example: one student wanted to deal with password overload – a clear problem with which we are all familiar but his outcome was a set of guidelines on how to construct good passwords but in my view that was a trivial answer to the problem because those guidelines can be found almost anywhere and it is doubtful if that goes anyway to solving the overload problem.

6.3 Project Target

When you think of a problem you normally do it in relation to its effects. It follows that you have to think very early in a project about what effects will be generated if you can resolve the problem – these real world effects are called the project target. Normally one settles on one major target although it is permissible to list more than one. Targets are effects so these are typically introduced by a verb form (increase, reduce, remove, reduce etc) and tend to be such things as: improved accuracy in data entry, to gain infrastructure resilience, streamlined workflow and so on.

6.4 Project Outcome

It is obvious that at the start of a project we do not have its outcome – but we can have some idea what its form may be. Therefore if we know our target we can speculate about what could be generated as a project outcome that might generate or go some way to generating the desirable target. It follows that whatever we

decide is the form of outcome we are looking for in the MSc project it must credibly be able to generate the stated target. Outcomes are objects and so are typically expressed as nouns: Here are some examples:

The target of “improved accuracy in data entry” might be generated by a project outcome of a training needs assessment report or a training plan.

The target is “to gain infrastructure resilience” might be generated by a project outcome of a revised backbone design or a set of recommendations for new technology.

6.5 Problem, Theory (Speculation) and Form

It is often useful when thinking about the solution to a problem theme to think of it as based around or generated by some personal theory a person holds about that problem and its setting. Essentially, one gets at this theory by speculating about causes and possible solutions routes. It is not easy to say how to speculate but it can be said that it is aided by a thorough literature review, personal experience and a deep consideration of the problem theme perceived in a given situation.

For example suppose the situation was related to issues with application software implementations in business not being as successful as expected. Recognition of this problem theme is a first step but if one is to do something about it, it might be useful to thoughtfully speculate on why success is lacking in this area. It follows that one might speculate that this lack of implementation success is due to poor implementation strategies, or poor user training, or poor project management or any number of things. Notice that there will always be rival speculative ideas and that is why one must be thorough in looking at the literature and using your basic knowledge and experience to open up the situation in order to at least have a credible theory as to the most probable solution route otherwise one might just waste time on chasing nothing of value.

Do not let this idea run away – this is not about natural laws of the universe such as Ohms law or Archimedes Principle – here one tries to establish a personal belief about a situation and its problem theme. So after speculation one might express ones personal theory about the above example as follows.

It is believed that implementation of application software is proving difficult and this may be due to poor implementation strategies. It follows that if this is the case and better strategies can be defined then implementations may prove more useful in the future.

Notice that my theory points to a particular form of answer to this problem theme and in this case it is related to perhaps a document that explains how to formulate implementation strategies based on a consideration of user needs, application intention and business objectives.

Occasionally, the theory may be embodied in a scientifically constructed hypothesis but more often than not in technological research it is expressed informally as an idea.

6.6 Primary Data

Primary Data is data is new data in the sense that it will not exist as a collection until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data collection is representative of some aspect of the area under investigation and can be processed to get a defined form of outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

6.6.1 Primary Data Collection Protocol

Within every project there has to be a collection protocol for the practical collection of the primary data. Every complete protocol will have 5 features:

Vehicle – this is the primary mechanism or technique employed by the researcher, typical examples are: interview, questionnaire, observation, role playing, seminar, focus groups, document searching and so on

Recording Profile – this describes how the data will be physically recorded. Typically we might use: written report/transcripts, formatted record sheets, video, sound recording, computer logging, excerpts from documents and so on.

Sample criteria –this is a profile that allows the researcher to know that he/she has a valid sample point from which data is to be collected. For example, if we wanted data on business uses of Digital Paper we need a profile of who we should ask for that information. If we do not have a profile we may not have any consistency in our data and it may therefore be meaningless.

Permission – you have to feel certain that the information you seek is legitimately available to you.

Ethical Profile – you need to be clear as to what you are doing, the way you are doing it and what you are asking for is ethically acceptable. Two things are at stake: the results may be biased and the results may not be acceptable.

6.6.2 Project Purpose in a Nutshell

Students sometimes get confused over what a Master's project is about. Consider a topic area like Digital Paper which is likely to be a very hot technology in 2006/7. A Master's project is not about producing a long narrative on Digital Paper explaining what it is, how it is used and what the technological infrastructure to support it might be. A Master's project is about identifying a problem theme in Digital Paper and then collecting and processing primary data into a form that helps you resolve that problem theme based on ones own personal theory. With this in mind, consider the following examples.

Example 1. Suppose I want to define all the various accounting functions so I pick up a manual for my in-house accounting system and then go through it looking for all the various accounting functions and listing them – is that primary data and is this a valid research purpose? No because in the first place one might just regard the manual as listing the functions anyway so in effect the data already exists, secondly, this is just one book and so its content might be complex, trivial or totally unrepresentative.

Example 2. So if I extract (my basic activity) instances of phishing (my problem theme) from an email log that would be primary data because even though the email log (secondary data) obviously exists, the list of phishing instances (my primary data) as a collection did not. My purpose being to process this collection of primary data to find out the most common sources of phishing and express my findings in an evaluatory report (my form of answer).

Example 3. If I conduct interviews in order to describe (my basic activity) a user purpose regarding illegal downloads (my problem theme) in my company with selected employees the interview transcripts are my raw primary data because the transcripts did not exist before the interviews took place. My purpose being to process this collection of primary data in order to develop a policy (my form of answer) to control illegal downloading activity.

Example 4. If I look through written reports (secondary data) on security violations (my problem theme) for a particular company with a view to identifying (my basic activity) the root cause of each violation then even though the violation reports exist the list of root causes (my primary data) did not so it is primary data. My purpose being to process that collection of primary data to create a strategy (my form of answer) that will alleviate or remove certain kinds of violation in future.

Example 5. If I plan to build an application for processing student MSc marks (my problem theme) then I need to ascertain (my basic activity) the system requirements (my primary data). My purpose being to process this collection of primary data to create a design (my form of answer) for the marks processing system.

6.6.3 Pre-processing Primary Raw Data

In many cases it will be necessary to process the raw data that one collects into a structured form of some kind so that is easier to use when generating the final project outcome. For example, if we have a series of interview transcripts it is obvious, that in that form, they are not easy to use so we might perform a pre-processing phase to get the core data into more structured form that then constitutes our primary data collection before the main processing phase that generates my project outcome is carried out. For example, suppose I examine company documents on misuse of IT system resources by employees. In this case I might proceed in two ways to get my structured primary data collection.

In line processing – that is I define my structure before I start and then as I come across a misuse example I structure it there and then. However, the disadvantage here is that you have to continually look back to see that you are not recoding the same data again and again from other incidents and so it tends to disrupt the collection process and make it longer to complete.

Pre-processing – here I wait until I have been through all the documents and then I use my set of notes to systematically work through the whole raw collection and form my structured collection that way.

6.7 Writing a Research Question (Study Projects)

This is intended to relate to the core problem that your research is trying to resolve. Make sure it is a clear question. Ideally one wants an open question: that is one that does not just end with a yes or no answer. This is often quite difficult to achieve but it can be done if you work at it.

A question is an expressions normally used to request information the form of an answer. Questions can sometimes be like commands used to elicit a response and others such as "Would you pass the salt?" looks like a question but in fact is a request or action, not for an answer. In Research Methods, however we will only look for questions that elicit information.

The simplest questions implicitly or explicitly request information from a range (finite or infinite) of alternatives and these are often called bi-polar questions. An interrogative word is a word used to start a question. In English the following is a list of interrogative words although some of them are rather old fashioned now.

Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, is/are, and can.

6.7.1 Questions that are not Questions

It is often difficult to write something that in English could be taken as a question. Now I am sure that in daily life everyone knows how to ask a question but when you write something down you are entering another world. Consider the following two lines – would they be understood as proper questions?

How to sharpen a pencil? Or What a pencil can do for you as a student?

Now these clearly ask for information but if you spoke these fragments to someone they would not quite see it as a proper question – in English such fragments would be understood as a kind of heading to a list of instructions for sharpening a pencil or a list of the benefits of using a pencil.

6.7.2 Basic Research Question forms

It is best when attempting to construct a question to think about what sort of answer is to be expected – now in normal everyday life we do this instinctively. For example, you would not say "is this the right way to Pablo's restaurant" if you wanted actual directions because that question form could only give you a Y/N answer. Instead you would probably say something like "how do I get to Pablo's restaurant from here" and reasonably you would expect an explanation to that question. Broadly speaking there are four sorts of answer:

Bi-polar answers - Essentially questions that imply a limited range of possible answers. Typically, a bi-polar question starts with a word such as WHAT, IS, CAN or DOES.

Is it possible to sharpen this pencil? (Y/N)
Does it make sense to allow children to sharpen pencils (Y/N)
Can a blue pencil be sharpened easily (Y/N)
What is the correct pencil weight for drawing a picture? (HB1, HB2 etc)
What is the common view of staff about using blue pencils? (Disagree, agree, etc)

Bi-polar questions can of course be useful but more often that not they have no great utility and the answer is obviously yes or no. Consider the question: "Can a green pencil be used in place of a red one?" Well of course it "can" be used so the answer is bound to be YES and so the question is pointless. Sadly, questions in this form occur all too frequently in student work and whoever writes such questions is not thinking at all about what information he/she want to elicit.

Explanatory answers – where the expected answer is an explanation and it is often in the form of a procedure or process. Typically, explanatory questions that start with 'HOW' or 'WHY'. For example, "How can a pencil be sharpened safely by young children?"

Descriptive answers – where the expected form of answer is a description most often in the form of an evaluation. Typically, these questions start with WHAT or WHY. For example, "What is the purpose of HB0 pencils?" (a simple explanation) or "Why are HB0 pencils difficult to sharpen?" (an evaluation)

Exploratory answers – where the expected form of answer implies an answer as an exploration of something. Typically, exploratory questions start with HOW or WHY. For example, "How should we use HB1 pencils best in drawing figures?" (often an exploration is needed here leading to an explanation)

Good interrogative words to start questions are: what, where, would, in what way, can, is it, why, which, where, how, does, who, why, do, etc – whatever word you use always ask what form of answer is implied by each of them. You must be sure that whatever form you decide on as answer that you can actually construct it and when it is constructed as part of your research it is in fact useful strategically in some way.

For example, suppose I decide that the form of answer I want is “The role of technological innovation is business success”. Well the task you now have is to now ask yourself whether you know how to express a role (write it down if you like) and whether knowing about this role will be of any use.

6.7.3 Research Question – Why are we asking it?

In normal everyday life questions come at us more or less all the time. Sometime we just answer them but more often that not we have a tendency to ask “why do you want to know”? It is therefore always useful when setting out your research question to ask why you asking it. That is you say to yourself, if I have the answer to this question then there will be some good outcome because of it. Sometimes we embed in our questions why we are asking them but mostly we do not. You will see later however, that you will have to make the reason plain in the aim so one might as well think it through at the question stage as well.

6.7.4 Research Question Form of Answer

For any Research Question there will always be several possible forms of answer arising out of ones personal theory about a problem situation encapsulated in the question. Ideally one would like the research question to be worded so that ONLY one form answer is possible and that is the one our theory suggested but often that is not easy to do so one normally has a range of options and competing theories to choose from so one looks for a form that interests you or looks to have the most utility. Do not be tempted to have multiple questions all in one sentence or look for multiple answers since it is better to focus on one significant output form. Table 4 lists the main forms of answer to help you when considering your personal theory.

Category	Typical Interrogatives	Expected Forms
Bi-polar	does, is, are, what, when or can	A list of possibilities
Explanations	how, why, who or where	A report, a model, an equation, a theory, a design, an evaluation etc
Explorations	How, who or what	A list, explanation, a comparison matrix, a pattern, a survey report, a theory etc
Descriptions	What, who or why	A report, a process or procedure, a model, a policy, a strategy, a theory etc
Table 5. Research Question Outcome Possibilities		

6.7.5 Strategy for formulating a Research Question

There is no easy way to do this and no real templates for it either so a good formulation will require some clear thinking and effort. What follows is a typical structure that you might use, but do not feel limited by it, and neither should you worry too much about the order in which you present the following elements although it would be very odd not to have the interrogative at the beginning (**SPITS** for short)

Spotlight – try to put the spotlight on where the primary data or information needed to answer the question might help come from.

Problem – this is about focusing on a single problem, so try to be as concise as you can.

Interrogative – what is your key interrogative word (how, why, what etc). You should note that some interrogatives need to use two words if a proper question is to be formed. For example, “how” on its own will not normally make a question but when you say “how can..” it is clearly a question.

Target – think about what will happen in the real world if you can resolve the problem. For example, it might be your target was to gain efficiency improvements, provide or enable better communication, increased accuracy and so on. It is also possible, but usually unwise, to state the target negatively if this makes the wording of the question more natural and you will see examples of this in section 6.7.

Suggestion – here one thinks about the problem theme and simply asks what sort of answer and what form it might take. So sort of answer might be yes/no, an explanation, an exploration, a description and these sorts of answer might be expressed at the end of the project as a report, a model, a list and so on.

Here is a good example from student work - "How can the billing cycle time be reduced by identifying and defining best practice in order to improve the quality of response to customers by reviewing the initial accounting processes stages?" Notice here that we have:

Interrogative = what, **Problem** - billing cycle time, **Target** – improved response to customers and **Spotlight** – initial accounting process and **Suggestion** – a best practice portfolio.

It is not always useful to add in the data spotlight because sometimes it can limit ones speculation about causes and solutions and in any case, the spotlight is often implicit in the problem definition. It is also possible and permitted to add in what form of answer you expect to the question but normally I would advise against that in most cases and this is discussed in the next section.

6.7.6 Function of a Research Question

The function of the research question is to crystallise the problem and desired effect (target) of any solution. But doing this is only useful if it allows the research enough room to theorise or speculate about possible answers so that indeed the solution space can be explored. Consider the following formulation:

"What factors influences the development of sound IT project management working relationships?"

Here we have in a solution because we are told that the problem is "working relationships" and what we want as a target is sound working relationships. But we in effect we are told to look for factors and so the solution to this problem theme will be a list of factors. The trouble with doing this is that it cuts off any further speculation about dealing with this problem idea and so the question becomes rather pointless.

6.7.7 Meaning in a Research Question

This section has looked at the structure of a typical Research Question but that is all it is and students must not treat it as some sort of template – it **MUST** be thought out step by step and even then one has to think does it make any sense, is it a focused question, what sort of answer should I expect and so on – there is simply no substitute for careful thinking.

Once you have formulated your research question and have a good idea what form the answer will take then its time to test it using the following ideas. Now be aware that this is just a test of structure and of itself it does not mean the question makes sense – there is no way to do that other than using your own brainpower and common sense – if it makes sense to you it will probably make sense to whoever else looks at it.

English – does it read correctly in English as a question?

Paraphrase – if it's a good question you may be able to ask it in several different ways – so try to do that until you get a formulation you are happy with.

Bi-polar – this means that the question has a fixed and limited range of answers such as "Y/N", "bad", "good", and "excellent". This type of question can of course be useful but the problem with them is that such answers do not have much utility – that is they do not tell you anything of value in terms of what action or actions you might take. You are advised to avoid such questions for your project.

Discussion – look at your question and honestly ask 'will this question produce discussion?' – what this means is to ask 'who am I writing this question for and would it interest them'. Try not to think that you are doing this for your Research Methods tutor but try to think what you would do if you were trying to get funding for research to get an answer to the question from someone.

Answer Form – try to work out what form or forms the answer will take (typically: bi-polar, explanation, description or an exploration) – if you try to avoid this aspect you may find yourself in serious trouble with your research.

6.7.8 Common Errors in Research Questions

The following are typical errors found in student written Research Questions – they can all be avoided if one takes just a minute to think through what has been asked and what sort of answer is likely.

Not a Question - to an English speaker the following would not sound like a question, instead it would sound like a heading to a list of instructions or a procedure. "How to make business application development productive at XYZ Corporation?"

Multiple Questions – It is never a good idea to try to put TWO (or more) questions into one as in the following example - one is about testing and one is about bugs they are quite different things. "How can software bugs be minimised and the testing cycle shortened in the development process of an Inventory System?"

Obvious Answer – these are cases when no research is needed because the answer is either obvious or common knowledge. Questions like this show a serious lack of thought – take the second example and it is easy to see that the answer to the question is bound to be YES - of course a productive work-life balance "CAN" (but might not) be obtained so there is nothing of any value whatsoever in a question like this. Similarly, it is easy to explain how a better development process can increase productivity.

"How can a better business application development process increase the productivity at XYZ?" or

"Can a productive work-life balance be achieved with telecommuting for technical personnel?"

Please remember that it is possible to write a very poor question that exhibits more than just one error type. Again, there is simply no substitute for thinking about what it is you have written.

6.8 Primary Data Generation with BAGeD

Based on a problem theme, theory and the form of the project outcome expected one needs to formulate a process to create a unified collection of primary data. There is no algorithm for doing this and one has to go carefully through the steps: define the data (BAGeD), locate the data and decide on a protocol to collect that data reliably.

Spotlight - The core of this primary data generation process is to find an activity whose execution effectively points to the right data so that you can formulate the whole collection plan around that activity. This core activity is called a Basic Activity for Generating Data (acronym BAGeD) and is the activity that one performs to generate the primary data that you want. Think of the BAGeD as a sort of spotlight that is focused just on the primary data that one needs and nothing else. That is the spotlight illuminates the data that you want in the sense it tells you how to generate primary data items but not how to actually collect that data.

With a BAGeD it is ideal if you can find just one verb to describe the activity. One needs to be careful here that the activity is clear since almost all verbs need to be qualified or supported by stating what the object of the activity is. For example, if I were to say, "look at fault logs for my primary data" then that is very indistinct because it does not tell us what to look for (the object of the looking). But if I say, "look at fault logs to describe instances of SPAM attacks" then I now have a more distinct activity because I know what I am going to write down as my primary data. The whole primary data collection process is then fitted around the BAGeD and the detailed planning to get the necessary data can then be made.

Example - suppose the problem theme is the value of training. Clearly a lot of money is spent on training so it might be really useful to know if there is a link between it and productivity. Suppose we speculate that the link is to do with essential business working practices and these change over time to meet new needs so that what I need is an answer in the form of a process model on how one identifies changes in business essential working practices and links them to a training initiative.

Now that I have my theory and form of answer (a process model) the Basic Activity for Generating Data can become **describe changes in essential working practices** of key operational staff – thus, my Basic Activity is "**describe**" and the Primary Data will be **changes in essential working practices**. In practice you might try several ideas before you are happy with one. Now I have this core activity I can work out the full process of getting to the data and processing the resultant collection to get my process model (outcome) that describes the link between business essential working practices and training.

Once the BAGeD is clear it, is an easy step to say how that data will be collected. In the above example I might use interviews with relevant staff. In summary the whole process becomes **describe changes in essential working practices** (BAGeD) using **interviewing** (collection protocol) with relevant staff.

6.9 Getting a BAGeD

The Basic Activity for Generating Data (BAGeD) then is an idea that allows you to spotlight exactly the data that you want. So we are looking for an activity and we hope that activity will shine a spotlight on the data. There are only three real considerations:

Problem Area Expertise – it is obvious that you need to have gained expert knowledge in the topic area and in the particular aspect related to the problem theme you are dealing with. In general, depending on the topic, this might include things such as: knowledge of the technology, management and usage processes. Unless you have thoroughly prepared by using literature reviews and/or other means you will simply not be in a position to know enough to be able to decide competently what data it is possible to collect.

Intended Outcome – fix in your mind what your Research Design is trying to generate as an outcome. With the above in mind, recall that whatever data you collect will be first formed into a structured primary data collection during the pre-processing phase, which follows immediately after collection, and then that structured collection will be used to generate your outcome.

Let us suppose the outcome is to be a set of guidelines, so you have to think what sort of primary data is needed to be able to generate the guidelines. This means you must know what guideline means and how one is constructed and that is where secondary data comes in. So in this case you might look at text books or journal articles to find a guideline model to use. Additionally, you would look at examples as well as look at any relevant company or international standards.

Collection Protocol – the last thing to consider is can the data be collected and if it so, what is the best way to do that. So it's not a matter of just choosing anything that comes to hand, it is a serious practical consideration based on a thorough and logical analysis of the sort of primary data that you want.

In the guidelines example above, the idea might be to use a questionnaire and one has to ask would a questionnaire allow for the collection of the data I needed. Let us suppose that the data we spotlight is: IT media and usage. Now it's obvious that a questionnaire can easily get media data but it is not clear how it could capture usage data so I might decide to get that information by interview instead because I want a much richer picture there. The point is that guidelines are largely about usage so that is where I must direct my effort.

To elaborate, usage is a complex issue and if you try to get it with a questionnaire you are going to have to have a very good idea what the usage processes are and so it may miss lots of things that are going on in the company setting. Whereas, if I use an interview, I have much more opportunity to explore the usage idea and that is what I really want.

6.10 Research Question, Form of Answer and BAGeD Examples

Consider the following further examples which focus on the BAGeD (your data spotlight) and linking it with some theorising or speculation about an expected form of answer. In each case several possible forms of answer are listed but in a research study only one would be chosen for further work.

One needs to be careful – this all sounds fine, even clever but a researcher must seriously consider if a complete process built around the BAGeD can be formulated in order to get at the necessary data within the time and other resources that are available.

RQ = What limits investment into e-applications for SMEs in Hong Kong leading to a loss of competitiveness?

- A list and description of investment constraints or
- A strategy to deal with the investment constraints or
- A feasibility report on e-application implementation or
- A post implementation review report or
- A prediction reacted to the effects of the constraints

Let us suppose that I choose a list and description as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on reviewing investment plans and the corresponding strategic plan in order to identify (Basic Activity) the possibility of an investment constraint (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to collect investment and strategic plans (secondary data) and by a process of review I identify and extract key investment decisions in the investment plan linked to a strategic plan. So my primary data will consist of a list of identified investment constraints, which I will need to explain.

RQ = How can IT operational criticality be monitored and controlled in order to build effective business systems?

- A process of data criticality categorisations or
- A user guide to data criticality or
- A DRP/BCP policy document or
- A report explaining how data and criticality are related

Let us suppose that I choose a DRP/BCP policy document my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on listing data categories and using these categories I review reported critical incidents related to data categories in order to match (Basic Activity) the category to the criticality of the incident (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to collect category data (secondary since they must exist in this case) and collect incident reports (secondary data) and by a process of evaluation of each report extract incident details and categorise them (my primary data). So my primary data will consist of a list of categorised critical incidents.

RQ = How can supply chain logistics be improved to provide continuity in manufacturing systems?

- A evaluation of a modern supply change process or
- A feasibility report on RFID or
- An implementation plan for RFID or
- A model that shows how improvements may be made using RFID

Let us suppose that I choose a list of implied benefits all explained as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on describing (Basic Activity) supply chain tracking problem themes (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to identify tracking problem themes and by process of evaluation of each problem theme I analyse how RFID might alleviate that problem theme. In essence I extract key reported problem themes and possibly categorise them (my primary data). So my primary data will consist of a list of categorised problem themes in supply chain tracking.

RQ = How can an improved personal communication protocols be established leading to productivity and business success?

- A feasibility study on IM and its use in offices or
- The definition of a training programme or
- A series of factors that must be in place before IM adoption or
- A cost/benefits report or
- The design of a regular monitoring scheme to assess effectiveness

Let us suppose that I choose a cost/benefit report as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on analysing (Basic Activity) call content with regard to costs (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to identify the sort or calls and then extract the cost (easy) and assess the benefit (hard) and by process of evaluation arrive at my report. So my primary data will consist of a list of calls and their associated cost and benefit.

6.11 Writing an Hypothesis

This matches with your research question and amounts to you saying what you think to be true in a given situation. It is in essence an extension of your form of answer where you try to say not only the form but what you think the answer will actually be. When you do this your work then become a process whereby you try to show that your hypothesis is valid. It is quite difficult to write a suitable hypothesis. There are three stages: firstly write the null hypothesis, secondly write the alternative hypothesis and lastly write down the dependant and independent variables. Unfortunately many new researchers seem unable to do these things satisfactorily. Let me illustrate.

A student wanted to write a hypothesis that essentially said that there was a link between IT certification training and personal productivity in support roles. He then went on to define the variables as: Role of IT (independent) and Personal Productivity (Dependent). Now this will ONLY makes sense if you can quantify the variables productivity (which is quite easy) and 'Role of IT' which it seems cannot be quantified. Now in research people tend to treat the idea of hypothesis in two ways and the second way is often quite valuable in many research situations.

6.11.1 Formal Experiment

To set up a formal experiment one creates or identifies two samples: one exposed to some effect and one not. For example, suppose I were looking at whether a new diet called lose-weight-quick worked or not. I could set it up a hypothesis and look for samples where some people were exposed to the new diet and some were who were not. The experiment then amounts to seeing if there is any significant difference between these two samples. (See notes for how to set up a formal hypothesis)

In a sense we are trying to prove the diet works but that notion of proof needs very careful understanding. The point is that it is very likely that the diet will work for many in the sample and not work for others. So our proof carries a qualification which is that all we could reasonably say at the end is that the diet is likely to work for a large number of people (or not as the case may be). A second point is that we do not usually do thousands of similar experiments and so at best our results for a limited sample would be tentative. Notice that this outcome is quite different from an experiment that sets out to verify a natural law like Archimedes principle or Ohms law where the amount of variety is much, much less and of course such natural laws have been tested many thousands of times so we are assured of their validity.

6.11.2 Informal Idea

Instead we could just have what might be called a tentative hypothesis that suggests that there may be a link and then use case studies to demonstrate this. Notice that we are NOT proving anything here only suggesting that something may be true.

6.12 Writing an Aim and Objectives

For each project we want one overall aim and a set of objectives that collectively will generate the form of answer that has been defined (project outcome). An aim/objective is expressed as an activity to get to a defined and measurable outcome within the scope of the project. The essential difference is that the aim expresses the target (or purpose) for the whole project outcome whilst objectives perform the same function within the project itself. Every time you write an aim or and objective you have to ask three main things with the abbreviation JOB – so when you write an aim or objective make sure you do a good JOB of it.

Can Justify – this really amounts to asking if the aim/objective make sense in that it generates a minor project outcome within a particular aim.

Can Observe - Make sure than someone else can observe or check what you have done, normally this means you can document it in some way (in words, diagrams, charts, graphs etc) in your project document. For Engineering projects this also means that the application is visible to all markers.

Can Build - Make sure that YOU can build the outcome stated.

6.12.1 Project Aim

This derives from the project problem definition and is best thought of as expressing the overall activity and intention of the project to generate an outcome that can be placed in the project document or made easily visible to the examiners. It has a number of elements as follows although when you write your aim you do not have to do it in the same sequences as expressed here and you may write it in any way that best captures your ideas although doing it in this sequence tends to be more logical.

You will note in the aim structure that follows that the problem theme is not explicitly mentioned and we infer what it is by looking at the target. The reason it is not included explicitly is that when one does one tends to get very awkward constructions linking problem and target so we might see absurdities such as “to improve website accessibility because web site accessibility is problematic”. The structure of a good aim is as follows where we can use the acronym ASOT to remember it.

Activity – what must be done with the available data to get the project outcome? Ideally, look for a single activity that sums up the whole project process for generating the intended outcome.

Spotlight – where will the basic data used by the activity come from?

Outcome – this element says how the project outcome will be expressed knowing that this outcome will later be used to generate the real world target. If the Research Question expects a model as an answer then the aim must have the same form of generating the model. Similarly, if the application description states a system to do X then the aim must have the intention of generating system X.

Target – what is the real world intention? That is the project outcome should be useful in the sense that it addresses the real world problem theme on which the project is based.

Aim – to create a website structure design using cascading style sheets in order that it might be used in design to improve web site accessibility.

Activity = create, **Spotlight** = cascading style sheets, **outcome** = web site structure design and

Target = to improve accessibility.

Sample Aim 1 – “To create an improved network infrastructure”. This is unsatisfactory because we have no target - we know that there will be an improved infrastructure but we don't know what effects that will have. So is improved infrastructure the outcome – it cannot be because it would imply sending to Portsmouth for marking some object called “improved infrastructure” and that is an absurdity. So here we have no target and no outcome and we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

So if I just use the above example it would be possible to have a target of a reduced network down time because of the Improved network infrastructure but that could ONLY happen after the project completes and in the project one could generate an infrastructure design - now that can be completed within the project period and later used to build the infrastructure which can then be used to generate our reduced network down time. Another factor here is that we cannot measure whether something called improved network infrastructure (what scale would we use?) has been achieved unless we have a target such as reduced down time which of course we can measure.

Sample Aim 2 – “To build a Wi-Fi implementation strategy”. This is unsatisfactory because although we know the project outcome is an implementation strategy we do not know what value it has in the real world because we have no target. Notice also we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

6.12.2 Project Objectives

The aim expresses the overall outcome for the project but to get there we normally have to pass through a number of minor outcomes on the way and these are expressed as being generated by objectives. For example, an objective that sets out to build a model of the software construction process could easily be a minor outcome for a project dealing with the construction of web sites but could also stand on its own in the sense that is a useful outcome whether the project is completed or not. Conversely the design of a set of interview questions is most likely not to be an objective but a simple project task since it is something that needs to be done but only has meaning within the project.

Since we are looking for minor project outcomes that collectively deliver the project outcome we have a little problem here because any project is made up of a series of tasks, some of which will generate a minor project outcome and some will not. For example project tasks range from preparing the contents list to evaluating the project outcome. A possible rule for deciding if a task leads to an objective is:

Ask is the object produced by the task something that could stand on its own outside the project and in that sense valuable in its own right?

If the answer to the first is “Yes” then it is likely to be a task that leads to an objective. Please take care; this is just a “rule of thumb” so look for things as minor outcome that are real milestones to getting the project finished. It may be useful to think of the project as a pyramid where the final project outcome is at the top and below it are layers that have been generated progressively from objective minor outcomes so that we eventually get to the top.

The format for an objective is much the same as for an aim but with no target and two added features in that they must be progressive and bounded. There is only one aim but there may be from 3 to 6 objectives that show a progression that leads us to the overall project outcome.

Progressive – objectives must build sequentially so that collectively they amount to reaching the aim.

Activity – Ideally we look for a single activity that will generate a minor project outcome that can be expressed in a form that can appear in the project document

Spotlight – what is the data area focus of the objective's activity?

Outcome – In this element you say how the outcome of your objective will be expressed knowing that this must be in a form that can be written into the project document.

Bounded - objective outcomes must be achieved and available within the project period and must not refer to anything that might occur after the project document is completed and submitted

Example – To model and document the software development process.

Activity = model, **Spotlight** = software development process, **Outcome** = a document, Bounded – yes we can do this activity within the project period (in this case we cannot show progression as that only applies to the complete collection of objectives)

It is easy to become completely muddled with objectives and one source of this muddle is the distinction between a project objective: one about what a student can do and evidence in the project document and operational ones: those that have some real world effect that might happen after the project has been completed. In simple terms if you set an objective in your project it must be completed within the project's time scale. Let us just take an aim and look at some possible objectives.

Aim = To report on how the bicycle is an aid to mobility in a modern urban environment

Sample Objective 1 – “To list in a report the components of a modern bicycle”. This is fine since clearly it is something that you can do and evidence in a project document so somebody else could check what you have done.

Sample Objective 2 – “To describe how a bicycle functions”. This is no good since although it is clear that you can develop a description, no one can check it unless you write it down. Better to say “To describe by means of annotated diagrams how a bicycle functions”

Sample Objective 3 – “To understand how a bicycle helps urban workers”. This is no good because although you can do it no one else can check it. Better to say, “To prepare a report explaining how urban workers could be helped by the use of a bicycle”.

Sample Objective 4 - “To ensure that workers get to their office on time by using a bicycle”. This is no good because you cannot do it and if you cannot do it no one can check what you have done. It also sounds more like an aim than an objective because it hints at a target. Better to say “To report on bicycle usage strategies that might be applied by urban workers to ensure they get to work on time”.

Sample Objective 5 – “To implement a bicycle repair system”. This is no good since you can clearly do it but it cannot be checked in your project document. But you could say “Report on the implementation of a bicycle repair system” or “Produce a design document for the creation of a bicycle repair centre”.

Sample Objective 6 – “To ensure that bicycles conform to BS 7898”. This is not really much good as it is in essence a requirement and not something that one can do within a project itself. However, one might have written “To prepare a report showing how a bicycle can be evaluated for BS 7898 compliance”.

6.13 Words needing care in Aims, Objectives or Research Questions

The key thing is to look at the main verb (activity) you are using and ask ‘does it tell me what to do as a practice’, if not then its use is suspect. A good way to assess if the verb is strong enough is to connect it with an outcome. So we might write ‘Create a framework...’ – here we have the activity ‘create’ and the ‘outcome’ a ‘framework’ and it is easy to see that it can be done.

6.14 Writing a Title

The title is the name of your project – rather like the name of a novel, something that catches a potential reader’s attention but just gives a hint as to what the work is all about. Think of it as a kind of nickname or slogan for your project and as such it is not a good idea to try to use the same set of words for the title, Research Question and aim. Titles typically have two elements:

Aspect – this is the particular focused area of your study

Why – this says why it might be a useful aspect

Mentioning the means by which you solved your problem should only be included in the title if it is crucially important. As an example, suppose your project was concerned with the development of a database and you used Microsoft Access. Unless your project compared your product with a similar database implemented in Oracle, say, then the tool you used to solve the problem is not as important as the problem you set out to solve.

Be careful with titles, there is a tendency to use the title to say what you will do. The purpose of the title is to give a concise name to what you do. Avoid noise words or phrases such as: “A report into...” (redundant: of course it is a report!) or words like “study”, “investigation”, “enquiry” and “development” are often similarly just noise. It is also usually very unwise to express the title of your project as a question although a title in the form of a proposition is often quite useful as in example 1 below. Here are some examples of good titles:

Planar Similarity – A Possible Software Quality Measure
Heuristics in the Stages of Soft Systems Methodology
A Taxonomy of Heuristic Problem Solving

7. WORKBOOK 7 – BASIC RESEARCH METHODS CHECKLIST

In research we are usually trying to do one or more of the following: understand something, explore something, describe something, explain something, improve something, build something or prove something. To do any of the above, you will have to decide what data you want to collect and choose rationally a research method as your primary research vehicle and build a research design around it.

You need to exercise care here so as not to become confused between a Research Method, which is a framework or model for the whole research project, and Data Collection Protocols, which are vehicles for actually collecting the primary data and might include such things as interview, observation, questionnaire, seminar or role playing.

What follows is just a summary of the methods and further information can be found in the associate project notes and there are many books available on each of the methods listed below. There are many research methods but the list below presents the major ones.

7.1 Research Styles

This is a practical notion and you would be wise to think project ideas through in terms of these styles. There is no sense that one or other is superior and no reason why both should not be applied at the same time.

Quantitative – a style that represents information in numerical form. The numerical form might be graphs and statistics which can be used to show trends, comparison and similarities and the graphs might lead to equations which link variables or allow one to make generalisations.

The advantage of quantitative data is that there is solid evidence that can be permuted in a variety of ways to support or not support a contention. In general, one is counting the frequency of some event – say the number of times the user selects the wrong icon but, and it's a big but, the data is only truly valid in the context in which it was collected so one needs extreme care if we want to generalise.

Qualitative – is typically used to analyse how certain actions occur not just how often they occur. The information is usually represented in textual form of some kind as a description of some observable event or events. The usefulness of this is that it exposes the thought processes or reasoning behind a particular behaviour – why a user clicked the wrong icon. However, it does make the analysis and representation of the data more complex.

Although these are defined, in practice one does not usually start by thinking about the style and typically as you think about the problem and what primary data your research will collect to deal with it then it tends to define itself as predominantly quantitative or qualitative.

7.2 Research Approaches

There are two broad approaches to research, which is always essentially exploratory. In practice you do not decide the approach as such and it will effectively be decided for you when you formulate your research problem and construct your research design. However, we may loosely define:

Deductive – in the sense that we have a theory that we want to prove – in simple terms deduction amounts to a valid argument – that is if its premises are true then the conclusion automatically follows. Typically we form what is known as a null hypothesis. That is we set up our research question in the form that there is no effect of some parameter. For example, I might want to look at the significance of scripting languages on system development time. I could do this by setting up a null hypothesis that says 'I contend that the use of scripting languages have no effect on system development time'.

Inductive – in the sense that one hopes that the theory emerges from the data analysis as we go along. It follows that we don't have a hypothesis we just know that we want to explore a certain domain to see what emerges. For example, I might want to investigate the fact that students are not attending chat sessions but I have no idea why (I don't have a theory) so the whole point of doing the research is to explore the issue implied by the question and hope that something will emerge as I go along. So induction is a kind of grounded argument, the truth of whose individual premises would not *guarantee* the truth of its conclusion, yet one hopes that it would provide some evidence for it.

In short we might say that deduction is an outlook we take when we are sure that we know what the outcome is going to be but Induction is an outlook we take when we can only feel probable about a given outcome.

7.3 Research Outlook

Before we look at the various research methods it is useful just to records that there are two approaches that are available to a researchers.

Hypothesis Driven – this is the classical research paradigm where we have by some means devised a theory or speculation of some kind and the research is then directed at trying to show that the theory or speculation is valid. For example, we might theorise about who buys Gel Pens and then try to show that it is true, or more usefully try to explain in a report why it is true

Data Driven – it often happens that when we embark on research we don't have a hypothesis which we are setting out to test. This is very common today where corporations have vast databases and want to see if there is anything useful in there that might for example lead to competitive advantage. It follows, that in these cases we don't start with a hypothesis but we examine the data sets looking for patterns or outliers or indeed anything that might allows is to formulate a theory of some kind. For example, we might look through millions of sales transactions and then to hypothesise that people who buy Gel Pens all have beards and wear glasses. If this theory is true we can better target our Gel Pen products.

7.4 Which Method to Use?

There are many methods/models that we can use for setting up a research idea, the most common being: case studies, vignettes, action research, experiments, quasi-Experiments, surveys, biographies/histories, grounded theory, ethnography and requirements gathering. It is never easy to decide on a method or perhaps more than one method, but the following may help you to make up your mind. Start by asking what exactly are you trying to do or find out? This will help you decide whether you need a qualitative or quantitative approach. So here are something you might consider:

Choosing a method will depend on many factors such as: context, available literature base, basic research purpose, is the domain changing rapidly, time available, skill available, sampling and other practicalities, access, your personal stylistic inclinations, reason for the study, what kind of outcome you want, cost, quantitative/qualitative, scale, control, sensitivity of the data and so on. Notice these factors are almost all about practical things - the whole point being that a design has to be carried out and that means it has to be practical.

7.5 Research Basic Purpose

In research, usually we try to do one or more of the following: understand something, explore something, describe something, explain something, illustrate something, improve something, build something or prove something. It is therefore very important when you are trying to decide on a method to keep this basic purpose uppermost in your mind.

7.6 Rationale: Case Studies

The case study method focuses on just one, two or twenty examples – such as your place of work, or one element of your organization or several aspects of a problem area. Typically:

1. Case studies are commonly used to **illustrate** or **understand** a problem or **indicate** good practice.
2. Case studies always have a context so make sure you are aware of it.
3. Case studies are usually qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain or describe some activity or phenomena.
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. There are broadly speaking two ways to begin case studies. This first is that you can set criteria and then go looking for relevant cases or secondly you can design and create the cases.
7. For most case studies there is usually be a longitudinal element - that is the cases will run over a fixed time period and you will periodically visit each case to collect the data.
8. There are several kinds of case possible:

Unique – implying that the setting and context are extremely rare and there may no be another chance to study this problem area again.

Critical – implies an important theory that you want to test and a particular case fits that profile.

Representative – implies that the case profile represents a typical or everyday situation.

Revelatory – implies that the case profile allows a researcher to study a situation never before looked at in detail and its context may be come common.

9. In practice you can use the following to organise your cases but remember once you have your case design you will need permission from whoever is necessary.

How many cases – be practical because there are time limits.

Case Criteria - add as many criteria as you think necessary to pin down the data location but don't have so many that you will never find a case that fits.

Sample criteria (collection protocol) – add as many criteria as you need to pin down a particular sample point where a unit of data can be obtained.

Visit Frequency - each case must be visited to get the data so work this out by looking at how much total time is available for the study.

Data collection Vehicle – by observation, interview, document analysis, etc. You will have to have a protocol to say when a valid sample arrives.

7.7 Rationale: Vignettes

These are perhaps best thought of as micro case studies or snapshots that illustrate just one idea and almost always are qualitative in their application. Typically:

1. Vignettes are commonly used in research contexts where actions, motives and judgements are to be explored, often in sensitive situations and you want to extract and **describe** examples or **illustrations** of significant elements in that problem domain
2. Vignettes always have a context so make sure you are aware of it.
3. Vignettes are essentially qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain, test an idea or describe some activity or phenomena.
5. Typically you cannot control and indeed have no desire to control the events being looked at but the events should be contemporary.
6. Vignettes enable participants to define the situation in their own terms or for their needs.
7. Most vignettes are "one off" events and as such act as indicators of an idea rather than as some sort of proof of concept. Therefore, this may also be useful when only a small sample is possible.

7.8 Rationale: Action Research

The main purpose of action research is to improve identified practice in some way. Typically:

1. Action research is commonly used to conduct research at the workplace with a strong desire to **improving** aspects of your own or colleagues' work so
2. In this kind of research you must be in control of events and they must be contemporary.
3. Typically indicated as useful when the research question starts with 'how' and there is a desire to explain something and use that explanation to improve practice.
4. Because of its setting, it is obvious that the research design is linked closely to its context.
5. The whole point of doing action research is the research leads to change in practice.
6. The working strategy is: plan something, do something, observe the something and reflect on what has happened as a result of your actions.

7.9 Rationale: Experiments

This form of research is used where there is a hypothesis and an associated variable that you can control (the independent variable) that will produce a change in some other variable (the dependent variable). That is the whole idea implies that you can intervene by altering or controlling the independent variable. Typically:

1. Experiments are commonly used when you want to **prove** or at least **indicate** that something is true. In practice proof is very difficult as it would imply that your findings are true for everyone, everywhere and for all time and so then tendency is to say indicate rather than prove in most cases.
2. In very simple terms one forms two groups: one which is exposed to the intervention and one which is not and then we observe if there is any difference because of the intervention.
3. Typically indicated when the research question starts with 'how' or 'why'.
4. The researchers must be in control of the events being looked at and they must be contemporary.
5. The biggest risk is that there may be other variables involved which we are not aware of.
6. It is difficult to be sure that our sample is representative.

7.10 Rationale: Quasi-Experiments

This form of research is used where there is a hypothesis and associated variables but you cannot control any of them. It would be nice to think we always had time and resources to run a carefully designed experiment but unfortunately this is often not the case. In an experimental design one chooses the samples involved randomly and thus one has control. However, it may be that data already exists and you can test your theory on that existing data or it may be that you simply cannot get control over all the variables that you want. So an experiment and a quasi-experiment are very similar it's just that the quasi-experiment does not quite have all the trappings that a full experiment has.

7.11 Rationale: Surveys

This form of research is used when we want to ask a group of people a question or questions. Typically:

1. Surveys are commonly used when one needs to get and express an overall **understanding** of the properties in a given domain.
2. One could of course also survey 'things' as well as people.
3. Surveys lend themselves to future replication.
4. Typically indicated when the research question starts with 'who', 'what', 'where', 'how' many' and 'how much'
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. Questions must be well-designed and unbiased and may be asked by interview or questionnaire.
7. Be careful to distinguish questions that are asking for facts and questions that are asking for opinion
8. The results will be very dependant on having a big enough and representative sample.
9. Be clear as to how the data will be collected – by observation, interview, questionnaire, etc. You will have to have a protocol to say when a valid sample arrives.

7.12 Rationale: Biographies/History

This form of research is used when we want to trace an historical event and analyses/evaluate its history as this may lead to insights or explain certain action so that lessons may be learned.

1. Biographies/History are commonly used to form a **description** and **explanation** of events.
2. One can use this to look at individuals or organisations or even technology.
3. Typically indicated when the research question starts with 'what'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. Be clear as to how the data will be collected – by documentary study and interviews are common.
7. Histories are naturally chronological and are characterised by epiphanies (pivotal events) and almost always exists in a context.

7.13 Rationale: Grounded Theory

Here the main idea is to use research to arrive at a theory based (grounded) on collected data. Grounded theory is quite difficult to understand and practice.

1. Grounded theory is used in situation where the theory is unclear or even unknown and so there is a need to **explore** seeking **description** and **explanations** in a domain.
2. One can use this to look at organisations or technology.
3. Typically indicated when the research question starts with 'why'.
4. You cannot control the events being looked at but the events need not be contemporary.
5. This is typically a qualitative study.
6. Be clear as to how the data will be collected – by documentary study, interviews, questionnaires etc.
7. Grounded theory is systematic in that the idea is to gradually move closer to a position where we can suggest a theory or proposition.
8. The basic unit of research is the category which is something that may represent a unit of information and might be almost anything.
9. The essence of grounded theory is in its data processing where various forms of coding are used to gradually unlock meaning in the data.

Open Coding – essentially the formation of the initial categories of information – it is characterised by looking for properties or asking when the something is a dimension of the research space.

Axial Coding – this is about trying to assemble that data after open coding. This can be done by using a diagram or some logic that connects things or looking for causes or looking for contexts and consequences.

Selective Coding – here the researchers invents a plausible storyline that integrates the categories in the axial coding model.

Matrix – a final step (though often omitted) is to produce a conditional matrix that is supposed to make clear the social, historical, technological or economic conditions that prevail in a situation.

Theory – one hopes that as a result of all this processing a theory will emerge which of course may go on to be tested by a formal experiment.

7.14 Rationale: Ethnography

This form of research is used when to immerse ourselves in the day to day life of an organisation or group. In this context ethnography is a description and interpretation of a cultural or social group.

1. Ethnography is commonly used when we want a reflective **description** expressed in an **interpretive** manner.
2. One can use this to look at individuals but more typically organisations.
3. Typically indicated when the research question starts with 'why'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. You may alter the events being looked at because you are normally a participant observer.
7. Be clear as to how the data will be collected – by participant observation.
8. Ethnography is about immersion in a culture: behaviours, language, structures and functions.
9. In such studies one often encounters gatekeepers, key informants and communication relies on a sense of reciprocity by investigator and his subjects.

7.15 Rationale: Requirements Gathering

Requirements are simply a statement of a systems service (what it must do) or constraints (what it does not necessarily do). In practice saying what a system must do is often extended to how it will do it. This method is a form of action research but it differs in that the only contact one has with the people involved is at the requirements stage and possibly at the implementation stage though this may vary depending on the systems life cycle employed. You should use this method when you are setting out to build an application of some kind such as a computer application. There are 4 stages of requirements.

Functional Requirements - These are requirements that say what a system does or is expected to do. Typically this would involve or include most of the following: process descriptions, details of all inputs/outputs and details of all the data that must be held in the system.

Performance Requirements - This is usually understood to mean requirements that describe aspects of the system that are concerned with how well it provides the main functional requirements. For example: performance criteria such as response times or how long it takes to print a report, data throughput and storage needs and security considerations.

Technical Requirements - This aspect of requirement looks at the tools and method used to build the system. For example, it may happen that you have to use a certain database package or for other reasons you need to select a particular scripting language and so on. More often than not this aspect amounts to looking at technical constraints that must be applied in building the system.

Usability Requirements - Requirements that ensure that there is a good match between the system and its users. In most cases usability is expressed in terms of measurable objectives.

7.15.1 The Requirements Document

The system and software requirements are usually documented in a formal manner so that ones understanding may be communicated to customers and system builders. The requirement document describes the following:

Services and Function – that the final system must deliver.

Operational Constraints - under which the system must operate.

Development Constraints - on the process used to develop the system.

Properties of the system - in the sense that it may have unplanned additional functionality.

Links - definition of other systems with which the system must integrate.

Domain - Information about the application - for example how to carry out certain tasks.

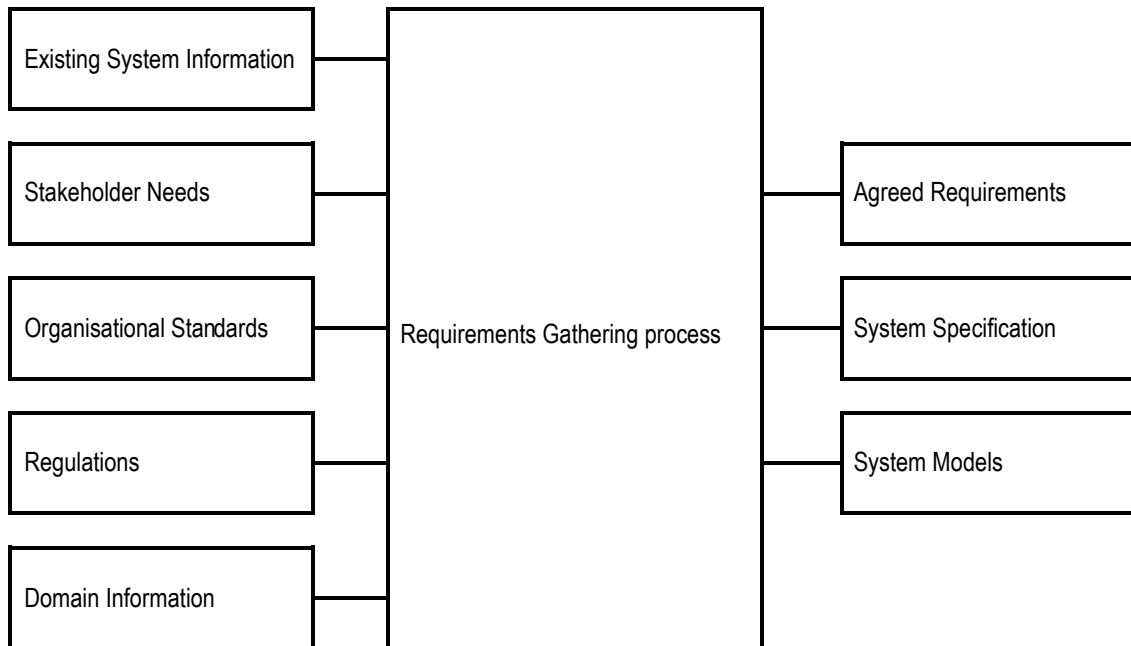

Definitions – acronyms, abbreviations etc.

7.15.2 Stakeholders

These are people who will be affected by the system and therefore should have a direct or indirect influence on the system requirements.

7.15.3 A Process Model

As a process model we might define the requirement process as follows.

7.15.4 Requirement General Questions

There are perhaps four general questions we might ask when attempting to gather requirements

Problem - What are the problems with the current processes?

Improvements - What are the improvement goals?

Reference. Kotonya, G. and Sommerville, I, (1997), Requirement Engineering, Wiley, ISBN 0-471-97208-8. This book is useful because it also contains excellent reading and reference lists.

7.16 Research Design

Finally, you must set out your research design. That is, explain how you will get your data – and this must be done in great detail. In summary, then, your research design is the blueprint of your research project which enables you to deal, systematically, with:

What questions to study?

What data is relevant?

What data to collect – you will need to work very hard here so that you can rely on your data.

Are there any practical limitations to what you can do

How to analyse the results – don't shirk this.

How to decide in which contexts your findings are applicable or can be exploited.

The main purpose of your research design is to help you avoid a situation in which the evidence you eventually collect does not address your initial question.

7.17 Research Process Development

It is quite common is many kinds of research but notably in Case Study and Action Research for the researcher's perceptions to change as data emerges. Often this will imply that the research design has to be changed or amended if it is to remain meaningful. These changes may be small such as a slight modification to the Research Question or aim but occasionally it may be necessary to make significant changes. For this reason researchers must always be careful in their design to allow a little flexibility if they can to accommodate possible unforeseen circumstances.

8. WORKBOOK 8 - BIBLIOGRAPHIC REFERENCING HARVARD APA

This workbook is a short summary of the APA style guidelines as contained in The Publication Manual of the American Psychological Association, 5e, 2001 (Subject Reference Collection: 808.02 AME).

The APA style is based on the Harvard referencing system whereby the date of publication follows the author name(s), and in-text references refer to items in the reference list using the author surname and date of publication, in brackets.

Referencing is important in all academic work as it indicates to the reader the sources of your quotations and borrowed ideas. Failure to indicate your sources is tantamount to plagiarism (literary theft). The purpose of the referencing system is to describe your sources in an accurate and consistent manner and to indicate within the text of your paper where particular sources were used.

Please note that there are two sections to this document:

How to **reference** correctly a source in the **bibliographic** section of your work

How to **cite** correctly a source in the **written** part of your work

Don't Get Caught Out! If you do not reference correctly you may lose marks or your work may be returned unmarked to you for correction. Therefore:

Keep a careful note of all sources used as you prepare your assignments.

Record all the details you need about a library book (including page numbers for any quotations) **before** you return it - someone else may have the book if you try to go back and check later.

Make sure you write down the source details you need on any photocopies or downloads you make.

Remember to print or save details of any website you want to refer to and record the date when you accessed the information.

8.1 Reference list (Bibliography) at end of Project/Dissertation

The reference list should be arranged alphabetically by author surname. The APA format requires book and journal titles etc. to be italicised, although we are not strict about that.

As a rule in projects and dissertations it is normal to produce two lists. The first is a reference list and that **MUST** only include sources you have cited. The second is a bibliographic list which includes all other sources you might have found but did not cite – this list is to allow the reader to explore the topic further if they wish.

8.2 Books

The details needed for a book can normally be found on the front and back of the title page. Make sure you locate the name of the publisher rather than the printer or typesetter. You need the name of the publisher in your reference list. Ignore any reprint dates; you need the date when the first, second, third edition etc. of the book was published according to which edition of the book you are using.

8.3 Journal articles

The details needed for a journal article can usually be found on the contents list, front cover or article itself.

8.4 Printed publications: Examples of References

The following are sample if how to correctly reference a source.

Book – pattern: Author, Initials. (year). Title of book. Place of publication: Publisher.

American Psychological Association. (1994). Publication manual of the American Psychological Association 4e. Washington, D.C.: Author.

Encyclopedia of psychology. (1976). London: Routledge.

Gardner, H. (1973). The arts and human development. New York: Wiley.

Moore, M. H., Estrich, S., McGillis, D., & Spelman, W. (1984). *Dangerous offenders: the elusive target of justice*. Cambridge: Harvard University Press.

Strunk, W., & White, E. B. (1979). *The elements of style* (3rd ed.). New York: Macmillan.

Note: Only list up to 6 authors. The 7th and subsequent authors are abbreviated to et al.

Edited book

Maher, B. A. (Ed.). (1964-1972). *Progress in experimental personality research* (6 vols.). New York: Academic Press

Article in edited book (Chapter) - The basic pattern for a reference to a chapter in an edited book (where the chapters have been written by several different people) is:

Author of chapter, Initials. (year). Title of chapter. In Initials. Name of Editor/s (Ed.) *Title of book* (pp.start and end page numbers of chapter). Place of publication: Publisher.

Vygotsky, L. S. (1991). Genesis of the higher mental functions. In P. Light, S. Sheldon, & M. Woodhead (Eds.), *Learning to think* (pp. 32-41). London: Routledge.

Encyclopedia entry - If the entry has no author, begin the reference with the entry title followed by the date of publication.

Lijphart, A. (1995). Electoral systems. In *The encyclopaedia of democracy* (Vol. 2, pp. 412-422). London: Routledge.

Government publication

Great Britain. Command Papers. (1991). *Health of the nation* (Cm 1523). London: HMSO.
Great Britain. Home Office. (1994). *Prisons policy for England and Wales*. London: HMSO.

Report

Birney, A. J., & Hall, M. M. (1981). *Early identification of children with written language difficulties* (Report No. 81-502). Washington DC: National Educational Association.

Conference paper in published proceedings

Borgman, C. L., Bower, J., & Krieger, D. (1989). From hands-on science to hands-on information retrieval. In J. Katzer, & G. B. Newby (Eds.), *Proceedings of the 52nd ASIS annual meeting: Vol. 26. Managing information and technology* (pp. 96-100). Medford, NJ: Learned Information.

Journal article - The basic pattern for a reference to a journal article is:

Author, Initials. (year) Title of article. *Title of journal*, Volume number - if there is one (Issue number), start and end page numbers of article.

Noguchi, T., Kitawaki, J., Tamura, T., Kim, T., Kanno, H., Yamamoto, T., et al. H. (1993). Relationship between aromatase activity and steroid receptor levels in ovarian tumors from postmenopausal women. *Journal of Steroid Biochemistry and Molecular Biology*, 44(4-6), 657-660.

Popper, S. E., & McCloskey, K. (1993). Individual differences and subgroups within populations: the shopping bag approach. *Aviation Space and Environmental Medicine*, 64(1), 74-77.

Weekly magazine article

Barrett, L. (2001, August 23). Daewoo's drive to survive in the UK. *Marketing Week*, 22-23.

Newspaper article

Caffeine linked to mental illness. (1991, July 13). *New York Times*, pp. B13, B15.
Young, H. (1996, July 25). Battle of snakes and ladders. *The Guardian*, p. 15.

Two or more works by the same author(s) with the same publication date - Where an author (or particular group of authors) has more than one work in a particular year, list them in title order and follow the date with a lower case letter a, b, c, ... For example:

Harding, S. (1986a). The instability of the analytical categories of feminist theory. *Signs*, 11(4), 645-64.
Harding, S. (1986b). *The science question in feminism*. Ithaca: Cornell University Press.

Anonymous works - If a work is signed "Anonymous", your reference must begin with the word Anonymous, followed by date etc. as normal. If no author is shown, put the title in the normal author position.

Note on source page numbers - Use pp. for page range only for encyclopedia entries, multi-page newspaper articles and chapters or articles in edited books. For articles in journals or magazines use the numbers alone.

Interviews and email messages - Because interviews and email messages are not considered recoverable data, you do not give details in your reference list. You should, however, cite an interview or email message within the body of your text as a personal communication: ...and this point was conceded (J. Bloggs, personal communication, August 22, 2001)

Legal References - Because the situation regarding legal references is complex and only US law is covered in the APA Manual, legal references will be covered in a separate guide.

Audiovisual sources: examples of references - Such sources are often complex but please note.

Films - The basic pattern for a reference to a film is:

Name of primary contributor - the director or producer, or both, Initials. (Role of primary contributor). (year). *Title of film* [Motion picture]. Country of origin - where the film was primarily made and released: Name of studio.

Reed, C. (Director). (1949). *The Third Man* [Motion picture]. United Kingdom: British Lion/London Films.

Spielberg, S. (Director). (1993). *Jurassic Park* [Motion picture]. United States: Universal Pictures/Amblin Entertainment.

If the film doesn't appear on the Library Catalogue, the Internet Movie Database <http://uk.imdb.com/> is a good place to check all the details needed for a film reference (follow the Company credits link to find details about the film studio/s involved). Alternatively, check Halliwell's Film and Video Guide.

Review of a film - If the review is untitled, put everything in square brackets in the normal title position and keep the square brackets.

Kinder, M. (2002). Moulin Rouge [Review of the motion picture *Moulin Rouge*]. *Film Quarterly*, 55(3), 52-59.

Malausa, V. (2001). Beauté du mensonge [Review of the motion picture *The Tailor of Panama*]. *Cahiers du Cinéma*, 558, 82-83.

Television programmes

Collinson-Jones, C. (Producer), & Dobson, E. (Director). (2003, July 14). Casualties of peace [Television broadcast]. London: Channel 4.

Single episode from a television series

This example shows the most complete information possible for a television episode. If details of the writer are unavailable, begin your reference with the name of the director.

Fraser, R. (Writer), & Geoghegan, S. (Director). (2003). Eyes wide open [Television series episode]. In P. Goodman (Producer), *Holby City*. London: BBC1.

Radio programmes

Portenier, G. (Producer). (2003, July 17). *Crossing continents*. London: BBC Radio 4.

Electronic sources: examples of references - The details shown below have been compiled according to the guidelines available on the APA Website (<http://www.apastyle.org>) in August/September 2001 (re-checked July 2003). Check this Website and the 5th edition of *The Publication Manual of the American Psychological Association* which is available in the Frewen Library for further guidance.

The basic pattern for a reference to an electronic source is:

Author, Initials. (year). *Title*. Retrieved month, day, year, from Internet address.
Banks, I. (n.d.). *The NHS Direct healthcare guide*. Retrieved August 29, 2001, from <http://www.healthcareguide.nhsdirect.nhs.uk/>

If no date is shown on the document, use n.d.

If the author is not given, begin your reference with the title of the document.

If a document is part of a large site such as that for a university or government department, give the name of the parent organisation and the relevant department before the Web address:

Alexander, J., & Tate, M. A. (2001). *Evaluating web resources*. Retrieved August 21, 2001, from Widener University, Wolfgram Memorial Library Web site: <http://www2.widener.edu/Wolfgram-Memorial-Library/webevaluation/webeval.htm>

Deciding your future. (2000). Retrieved September 5, 2001, from University of Portsmouth, Careers Service Web site: <http://www.port.ac.uk/departments/careers/plancareer/deciding-your-future.htm>

Electronic journal articles which are duplicates of the printed version - Use the same reference format as for a printed journal article but add "Electronic version" in square brackets after the article title:

Lussier, R. N., & Pfeifer, S. (2001). A crossnational prediction model for business success [Electronic version]. *Journal of Common Market Studies*, 39(3), 228-239.

If you are referencing an online article where the format differs from the printed version or which includes additional data or commentaries, you should add the date you retrieved the document and the Web address (URL).

Articles in Internet-only journals

Korda, L. (2001, July). The making of a translator. *Translation Journal*, 5(3). Retrieved August 21, 2001 from <http://accurapid.com/journal/17prof.htm>

Use the complete publication date shown on the article.

Note that page numbers are not given.

Whenever possible, the URL you give should link directly to the article itself.

Break a URL that goes onto another line after a slash or before a full-stop. Do not insert a hyphen at the break.

Articles retrieved from a database - Use the format appropriate to the type of work retrieved and add a retrieval date, plus the name of the database:

McVeigh, T. (2000, July 9). How your gestures can do the talking. *The Observer*, p.7. Retrieved September 10, 2001, from The Guardian and The Observer on CD-ROM database.

8.5 Citing references in the text

There are basically two forms. The first is when the author's name is naturally part of the sentence and the second when it is just a reference. References are made from the text of the paper to the full details of the work in the reference list in the following manner:

It is a contention of the paper, and this contention is supported by Williams (1995, p.45) who compared personality disorders ...

When an author, or group of authors, has more than one publication in the same year a lower case letter is added to the date. For example:

In two recent works Harding (1986a, p.80; 1986b, p.138) has suggested that ...

With two authors both names should be listed in each citation e.g. Duncan & Goddard, (2003, p.99)

With three to five authors name all authors the first time, then use et al. (and others). For example: the first time it would be Moore, Estrich, McGillis & Spelman (1984, p.33) and subsequent references to the same publication would use Moore et al.

For six or more authors, use et al. after the first author in all occurrences.

Note that when the in-text reference occurs naturally within the sentence "and" should be used before the final author.

When a source has no author, cite the first two or three words of the title followed by the year. For example:

... in the recent book (*Encyclopaedia of psychology*, 1991, p.62) ...

... in this article ("Individual differences," 1993, p.12) ...

Web pages where no author is given

However, if the author is designated as "Anonymous", cite the word Anonymous in your text e.g. (Anonymous, 1993, p.116).

When using quotations in your text

Try to observe the following methods.

Gardner (1973, p41) stated that, "The relative importance of the systems may nevertheless remain in approximately the same proportion"

Smith (1991, p84) found that "...there is no evidence that chimpanzees can produce a drawing and discern the object represented in it..."

Occasionally, very occasionally you may need to cite a work that you discovered in another work because you cannot find the source then observe the following examples:

Smith (1970, p.27) cites Brown (1967) as finding ...

Brown (1967), cited by Smith (1970, p.27), found ...

It was found (Brown, 1967, cited by Smith, 1970, p.27) that ...

If you need to use this form your tutors must approve it and you must show that you have made every effort to track down the primary source.

9. WORKBOOK 9 – WRITING UP A RESEARCH PROJECT

This document is in several sections covering everything from project supervision to grading.

9.1 Your and Your Supervisor

The student supervisor relationship is very important if a high quality project is to be the outcome. As a rule the supervisor will be interested in the topic area and will want to be active in its development although you as a student must do the work. However, your supervisor will not be expert in everything but will usually have some knowledge of simple statistics and the four main research methods: experiments, action research, surveys, case studies and application development.

9.1.1 Student Expectations

The normal expectation is that students have of their supervisor are as follows:

- Only be available for consultation for a limited time.
- Only supervise what the student does and not do the work for them.
- Advise on research design, scheduling and literature surveys.
- Advise on theoretical, conceptual and methodological issues.
- Advise on development of research skills.
- Advise on data collection, processing and analysis.
- Advise on ethical issues if they are relevant.
- Read, evaluate and be constructively critical of student work if given sufficient time.
- Have a good knowledge of the general area you are working in.
- Be in contact with the student regularly.
- Arrange if necessary supervision chat sessions.

For project students on distance learning programmes it will be possible to have meetings in the WebCT chat room, using IM or Skype where a full and detailed interaction can take place. These must be agreed with your supervisor and must be planned not to clash with other classes. However, some tutor may allow student to contact them any time they are seen to be online.

9.1.2 Departmental Expectations

Supervisors take a formal role and certain attitudes and actions are expected. In general they will:

- Visit the discussion board and email regularly within WebCT (at least 3 times per week).
- Set a mail forwarding address to their personal accounts in WebCT email settings.
- Devote at least 6 hours to the supervision process spread over the project duration.
- Conduct one-to-one chats as required with project students.
- Conduct student/supervisor communication within WebCT or their personal email account.
- Respond to a student query within a certain time frame (normally no longer than 3 days).
- Be familiar with all the project guidance notes and workbooks.
- Be familiar with the project chapter profiles.
- Make sure students know if they are to be away for an extended period.
- Be aware that students may make contact through any one of their three WebCT accounts.

The essence of online supervision adequacy is based on the quality of communication between supervisor and student with the intent that we want the learning experiences to be exiting, stimulating and self-rewarding. In practice this means that communication must be frequent, lucid, critical and yet encouraging.

Supervisors should be aware that if they set email forwarding in WebCT they will effectively get an automatic alert when there is mail for them. If the student has also set mail forwarding then supervisors will be able to reply immediately otherwise they will have to go into WebCT. However, there is no alerting mechanism if a student posts a question into discussion so supervisors must visit the site from time to time so as not to miss any messages.

9.1.3 Supervisor Work Reviews

Supervisors will read your written work. However, when they do this certain rules apply:

Finished work – you should supply your supervisor with written work as it is produced chapter by chapter but it must be finished work. In this context finished work means that the format and content are the very best you can produce and in accordance to the guidelines found in this workbook. The tutor's role is not to act as some kind of filter for rough work or polishing multiple drafts which you want to improve in effect making them do the work for you. If a tutor suspects that the section you have sent in is not in its final form they will return it to you without comment.

Action on Feedback – if you are given feedback on any part of your work then you are expected to study it with care and commitment. However, it is up to you how to respond or even ignore what you are told but in all cases the consequences that follow are entirely your own responsibility.

Responding to Feedback – in all cases you are expected to respond to feedback. This may take several forms: writing to your supervisor saying that you don't agree with him or perhaps offering further explanation or as in most cases making changes to the content or structure of your project document. When you make document changes in response to feedback they are to be shown **shaded** so your supervisor can easily see exactly what you have added or amended.

Questions to Tutor - your tutor will not answer any questions regarding whether your work is right, wrong, is it a pass, what mark will I get or is it good enough. The only thing you can expect in this area is that you tutor may advise you that the work is not ready for submission to the university. If this happens it will be entirely your own decision whether to submit or not.

Response from Tutor - in most cases you supervisor will only suggest that you do something or ask a question designed to point you in a new direction. Normally, the tutor will not supply you with any project content since that must be provided entirely by you. The reason is that the work is yours not the supervisors.

Preparation - Your supervisor will expect you to be familiar with all the notes and workbooks contents. You should therefore be careful that you don't waste supervision time asking questions to which you already have the answers.

9.1.4 Chat Session

Chat sessions for project students will usually be one-to-one and are typically used when there are particularly awkward difficulties – chat will NOT be the norm during projects and your tutor will have no expectation that chat will be used.

9.2 Overview of Project Structure

Here are some general guidance notes – they are NOT suggested chapters but general content guidance on the project as a whole and have a sharp process focus.

9.2.1 Introduction summary

This is about the problem theme and its setting, client context, topic area, personal theory, Research Question or application functional description and intended project outcome, general research orientation followed by a well-define aim and sound set of objectives. The introduction is to be precise, concise taking a discussion form that is explanatory and focused on giving readers a clear, coherent and comprehensive view of what the project is about.

9.2.2 Preparation for Research

This is your study of the topic area and research methods that you will need to know about. You will have to justify and explain the methods you intend to use; it is also your study of other people's work in the area that you wish to investigate - and a description of how you learned from their research.

Literature Review - What has been done before in this area - related to a particular problem theme and Research Question. This is all about preparing ones mind with all the topic area and research knowledge you will need.

Research Review - research into how the project investigation could be done and supported. At this stage student will already have an outline plan based on their approve specification but now the whole design must be thoroughly reviewed before actual work begins.

Knowledge of Alternatives – build a simple decision base which allows one to consider which methods could be used and how could they be used for this project.

Choices Made - which methods are to be used and rationally consider why they are good enough for the purpose.

9.2.3 Core Research

Here you execute the refined research design translated into a practical plan to obtain the collection of primary data and process it using acceptable methods into the intended project outcome.

9.2.4 Evaluation and Conclusions

This is the stage that looks at how one finishes off a project by a process of evaluation and the drawing of conclusions. In particular, it is needful to look at how one evaluates what was done and how it was done – that one needs to consider the project product (or outcome) and the project practice. For our purposes evaluating will be taken to mean reflecting on product and practice.

Many students confuse evaluation and conclusions but for a full consideration of the research work one must look at all project specific results and outcomes as well as practices and evaluate them and then perform the more difficult step of drawing generalised conclusion about both product and practice.

Evaluation of Project Product – the project outcome or product is normally evaluated against objectives, other existing products, using defined criteria or some form of expert evaluation. Additionally, one needs to be aware of any constraints that might have an impact on the applicability of the outcome

Evaluation of Project Practice - evaluation of project practice is more difficult than evaluation of project product and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way'. Additionally, one needs to be aware of any constraints involved, including time management that might have impacted on the use of best possible practices.

Conclusions - need to be considered thoughtfully as this is the point where one looks for implications and meaning that arise out of an attempt to generalise the findings.

9.3 Writing up your Project

The following sections describe elements that occur in almost all projects and which are generally important in constructing scholarly work. Do not be tempted to ignore these instructions – anyone who departs from the spirit of them may have their work returned for correction prior to formal marking.

9.3.1 Main Project Body Page Layout

The following example shows how each page of a project report should look, note that each chapter should start on a new page and that it is NOT necessary to actually say Chapter 1, Chapter 2 and so on as it is the heading that is important. Do not use numbering to greater than to three levels but you may use indented (but not bulleted ones) entries within a section at any level.

1. QUALITY CONTROL IN PROGRAM DEVELOPMENT

In this chapter the nature of quality will be discussed and its relation to physical measurable properties that might characterise quality.

1.1 INTRODUCTION

This project discusses a possible strategy for devising a program development methodology that goes some way to guaranteeing the qualities of the delivered system. In particular it will concentrate on just two aspects - that of developing generic designs and code and how such designs could be assessed for quality and function. The strategy is based on the simple premise as endorsed by leading authors in the field such as Blenkinsop, Wilson and Bowers that categories of problem can be identified and formalised. It is the contention of this report that such a process would more or less automatically:

Reduce - the complexity of the design process itself.

Ensure - the quality of the final product by:

Giving managers more control over the product development cycle.

Giving users more idea of the kind of system they are likely to get and much more say in what the shape of the product will finally be.

Releasing programmers from the drudgery of having to design the same piece of code over and over again, thus enabling them to concentrate their efforts on new

Formatting Note – you are encouraged to use these two forms of indenting: one with a heading in bold and one without as a means of structuring and indented section. The use of bulleted indents is not recommended anywhere in a project document.

1.2. Multiplicity of Design Factors

Every programmer has had the difficult experience of having to read and understand programs written by someone other than himself or herself. The sort of problem encountered may be aptly expressed in the following lines.

Everything has been thought of before, but the problem is to think of it again. (Goethe)

Many other authors, notably Frewin (1989) have discussed the notion of 'quality model ratios' and in essence this idea means that software systems have an implied model which can be accessed for

1.2.1 Multi-Tier Systems

In modern client sever systems

1.2.2 Interface Facades

In this case we look closely at the Internetetc

9.3.2 Plagiarism Checking

A software tool will check all your sources automatically and if plagiarism is suggested it will be dealt with very seriously since the reputation of the whole course and of the University is at stake. You must remember, that copying, paraphrasing, summarising and similar techniques where the material is extracted from a source must be properly acknowledged.

A simple rule is that if you use more than 6 consecutive words from a source it must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

9.3.3 Writing Abstracts and Identifying Keywords

The function of an abstract is to summarise your project, its context and its conclusions in order to give the reader an overview of the main project theme so that they can make an informed decision on whether they want to read the entire report. A good basic structure might be defined as follows but it will usually be limited to around 300 words.

What was the project about?

What did you actually do?

What were the conclusions?

It is normal to add keywords or phrases after the abstract to act as specific pointers to content. There are no particular rules about how to construct these words or indeed how many there should be but typically there are 5 or 6 and to be useful they must be chosen with care in the sense that they might in themselves be regarded as a sort of abstract of ones work.

9.3.4 Standard Appendices

Project reports MUST include the following appendices:

Your Project specification – it may be brought up to date from that submitted at the start

Your project plan expressed in an appropriate format

A glossary if this is appropriate

A full reference list of work that you cited

A bibliography (may be combined with your citation list)

Each Appendix should be introduced by a title where the number (12 in this case) should follow on from the numbering within the body of the report: **12. Appendix A – Project Specification.**

9.3.5 Typical Project Organisation

Below is a suggested organisation for your complete project.

Briefing Pages

Heading pages (examples follow later in the section)

Plagiarism declaration

Abstract for Report including keywords

Acknowledgements

Dedications

Content list (automatically generated) for all headings, tables and figures/graphs etc

Introduction:

Brief topic area outline and background to problem
Presenting Problem definition
Real World Target relevant to the problem
Speculation of problem causes and possible solution routes
Personal Theory on the best solution route
Research Question/Application Description
Discussion of expected project outcome
Scope of work
Aim & Objectives

Literature Research (see Workbook 5 for recommendation for various project styles)
Detailed consideration of elements that help you focus on your topic area

Research Design

Research Method and its rationale in dealing with the research question/application
Process to collect Primary Data
Processing of the Primary Data to get an outcome

Application Testing (Engineering project only)

Design of Tests
Test Results and conclusions to be drawn from testing.
Implementation plans

Results Discussion and Presentation (study projects only)

Discussion and presentation of results
Generation of intended project outcome

Evaluation (these are specific to what you did)

Detailed evaluation of what was actually done – your practice
Detailed evaluation of your project product/outcome including objectives not met
Met/Not met objectives

Conclusions (here one tries to generalise what was done)

Generalisations based on a consideration of both product and practice
It is also possible to examine the following minor conclusion elements

- Usefulness of literature sources
- Future work/development
- Relevant aspect of the course used during the project period
- Changes one would make if project were repeated
- What you have learned
- Value-added features

References and bibliography (see workbook 5)**Content of Appendices**

The following items must be in a set of Appendices. These may be bound separately if the composite document becomes too large (more than 100 pages).

- Code listings
- Project Specification and project schedule
- Inclusions (copies of relevant documents such as policies, invoice layouts, diagrams etc)
- Questionnaires.
- Summary interview transcripts
- Details test plans
- Requirement catalogues
- Glossary
- Other

9.3.6 Project Types Sample Outline Contents

Broadly speaking there are two kinds of project: engineering where you build an application of some kind and study based where one would investigate in depth some idea. Here are some sample contents lists that show chapter or section headings for the different project styles. However, if it is obvious that these samples have just been copied into your project with minor changes then your work will be rejected. See Workbook 9 section 9.3.5 for further general details.

Sample Study Style Report Contents	Sample Engineering Report Contents
Title: Internet Marketing – A Users View	Title: BrokerBase – Insurance Sellers Information System
Chapter 1. Introduction to Internet Marketing	Chapter 1. Introduction to System
Introduction and contextualisation IT marketing problem theme Problem Theme and target Speculation and Personal Theory Discussion and Exploration of Research Question Project aim and objectives	Introduction and Situation Overview Situation based Presenting Problem Application background and context Application overview Project aim and objectives
Chapter 2. Literature Review	Chapter 2. Literature Review and Application Scenario
Introduction to Internet Marketing Marketing Planning eCommerce Technologies and Tools Costs and Benefit Estimation Consumer Orientation and Market led operations IT supported Marketing and selling techniques Product, Price, Place, Promotion and Customer expectation IT supported Experiential marketing Security protocols and languages Auditing and secure payment systems	Outline of Insurance Brokerage practice Background Review of the Application Scenario Outline of Application Build Process and Tools
Chapter 3. Research Design	Chapter 3. Requirements Specification
Research Method Selection and Rationale Primary data collection process Data specification Data locations and expectations Collection Protocol Processing of Primary Data Collection Outline Results Project Outcome	Outline of the requirements (requirement catalogue into appendix) Research Plan for requirement gathering: functional, performance, technical and usability Outline Requirements catalogue Analysis and Evaluation of requirements
Chapter 4. Evaluation (Project Specific)	Chapter 4. System or Application Design
Evaluation of Project Outcome Evaluation of Research Methods and Protocols used	Principles used for this design Overall system design Build Process Overview Database design Component design Interface design including website
Chapter 5. Conclusions (Project Generalisations)	Chapter 5. System Implementation and Testing
Generalisations on the research Outcome Reflections on what was learned etc	Testing strategy Testing plans (detailed plan placed in appendices) Test results (detailed report placed in appendices) Application Implementation plans
	Chapter 6. Evaluation
	Evaluation of the application Evaluation of practice (methods and tools used)
	Chapter 7. Conclusions
	Generalisations based on the Application Reflections on what was learned Future work Etc
Notes	
1. Whatever the project styles the appendix must include: the project specification, glossaries, references lists, bibliographies. The appendices may be attached to the main report or they may be placed in a separate document.	
2. Remember these are just samples and you may well have different numbers of chapters and different heading and sub-headings	
Table 6. Sample Project Content Outlines	

9.4 Report Writing

In your research you will often have to write reports and of course you will have your final report to write. Reports are a special form of writing and therefore you need to note that reports are:

- Written for defined purpose.
- Written and targeted at specific audience.
- Written systematically to present your findings.
- Focused on what you have done.
- Information structured and formatted to lead reader quickly to main themes and findings

9.4.1 Structural Elements

The following tables are intended to give you some guidance on how to construct report in a scholarly fashion and in a way that leads to clear and concise presentation. It is important to structure all your work in a way that enhances its usefulness and utility. The following is a list of all the major structural elements, though there is no need to use all of them in every document you produce. The best advice is to choose a structure and then those elements that best suit the work in hand.

Structure	Description	Location
Title	A focused and short description of the document that summarises the deliverable element	Front page and above the contents list
Contents List	A short index based on the major chapters and/or sections	Before the main document begins but after the title page
Glossary	Used to list and describe special terms or abbreviations	Towards the end of the main document
Index	A detailed listing of all important words or phrases specifying location in main text	After the glossary if it exists otherwise after the main document
Appendix	For inclusion of explanatory notes, special documents or copies of originals	After the glossary but before the index
Footnotes	Notes at the bottom of pages and linked to pieces of text.	Immediately before the page footers
Headers	Standard text	Every page
Footers	Standard text	Every page
Keywords	Words or phrases used to form a simple classification of your work	Near front of report
References	List of all reference material in an approved manner	Toward end of document

Table 7. Main Document Physical Structural Entities

Organisation	Description
Chapters	Major elements in the development of the subject matter of the document
Sections	Minor elements in development of each chapter
Headings	Major Information Content indicators
Indents	Used to emphasise small but important points in the text
Bullets	Used to further emphasise an indented text
Tables	Used to represent important information concisely
Paragraph numbers	Used when it is necessary to reference all parts of a text
Page numbers	Used for indexing purposes
Diagrams	Used to show idea or data pictorially
Captions/Legends	Added to diagrams where necessary
Columns	Use when the subject material lends itself to such a view

Table 8. Main Document Structural Devices

Presentation	Description	Examples
Font	Letter style and size	May be proportional or fixed point
Renditions	Printed form of font	Bold, underline, italic, reversed
Orientation	Page format	Portrait or landscape
Form	Delivery form	Paper, electronic
Table 9. Main Document Structural Properties		

9.4.2 Report Writing Stages

There are a number of stages to writing a report and they require you to be focused on what you are trying to show as the core of your report.

What are your trying to show – this really goes along with the underlying purpose of your research question – typically this will be about wanting: to inform, to explain, to evaluate, to prove, to advise, to recommend, to predict or to bring about changes.

Collect and sift material – it is important to jot down ideas relevant to your purpose. These jottings will help you form an action plan for gathering information from other documents, visits, interviews, observation, surveys etc.

Note - information sources as you find them

Organise and structure the material - group your work into chapters, sections and sub sections. Make sure the order is logical.

Draft and edit/redraft – to get a good report you may well have to re-write it several times and this may include complete re-ordering. It is important that you need to be concise and use a formal language but it must be clear and concise. Use simple, straightforward words and sentence construction and make sure your spelling and grammar are faultless. Use clear headings and sub headings with bulleted indentations.

Thematic – make sure your work has clear themes that are easy to follow.

Plain English - do not try to be over-clever or fall into jargon.

Read Saunders chapter 13 pages 414 to 443. Don't skimp on this or I might skimp when I mark inferior work!

9.5 Summary and Advice

Your final project must have a strategic dimension. This does not mean you can't build some software but if you do it will be in support of a strategic objective. So whatever you decide to do consider:

Why it is being done but note it will not be sufficient to just say why, you will have to show evidence for your conclusion.

Cost/benefit is a useful idea but in most cases it is very hard to show benefits. In any case you need to look at other possible ways of showing that something is worth doing.

Don't forget life cycle logistics - that is what are the costs per hour (for example) of running a system for say a 10-year life.

Also look for impact for what you do. For example something might be cost effective but may have a negative affect on some business element.

Think through your ideas; don't be narrow - question everything.

Traditionally strategies are developed around two themes: needs - what are the business needs (at a high level) and what are the business values (what does it regard as important)

9.6 Project Submission Regulations

Successful project reports may lodged in the University library, it is therefore important that reports follow a standard binding format as described below. Project reports that deviate from these regulations may be penalised and returned to you for correction and in extreme cases, failed.

Submission - two full bound A4 portrait orientation copies of your report must be submitted by the defined dates. The report may NOT be submitted electronically – the copies must be sent by courier to reach us by the defined dates. However, you must also submit soft copies on either floppy disc or CD/DVD.

Presentation and Submission Checklist – your project report submitted using the correct form shown in Workbook 10. The form must be bound into your project.

Report Length - the maximum permitted report length is 15,000 words, which usually translates into around 50 to 100 pages (excluding appendices). If your report is likely to be significantly longer than this, consult your supervisor as to what to include and what to exclude. You are warned that should you exceed the permitted maximum length the University may return your work unmarked.

Binding - the project and any separate appendices should be securely bound using tape or book binding - if that is not available then plastic ring binding may be used. No other form of binding is permitted. Binding covers should be a card of weight of 140 gsm and the normal colour is to be RED but any other colour may used in case of sourcing difficulties

Front Covers Format - the front cover appropriately spaced vertically should conform to the pattern shown below using 24-point Arial Narrow with centred text and bold as shown. Do not include the square brackets when you complete these formats as they are just placeholders

University of Portsmouth

Technology Extended Campus

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[HEMIS No.]

Supervisor: [Name of supervisor]

Project unit Code [Project unit code]
[Month and Year, e.g. September 2004]

Title Page - the first project contents page, appropriately space vertically must contain the following information in the order shown below using 12 point Arial Narrow/Time Roman type throughout. Do not include the square brackets when you complete these formats as they are just placeholders.

University of Portsmouth

Technology Extended Campus

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[HEMIS No.]

Supervisor: [*Name of supervisor*]

Project unit: [*Project unit code*]

[Month and Year, e.g. September 2001]

Abstract - [The abstract of the project should be between 150 and 300 words in length and constructed to say what the project was about, what you did and what were the conclusions]

Keyword List - [List of appropriate key words]

Acknowledgements Page - it is common practice to add a page listing those you wish to thank for their help and assistance. As a rule acknowledgements should **only** be given to people who helped you directly with your work but were not involved in it. For example, if a colleague supplied you with a statistical analysis they should be acknowledged. However, it is not usual, necessary or desirable to acknowledge your parents, your friends or your supervisor.

Submission Form and Plagiarism Declaration

You must add the following two pages which require a signature. In practice one adds the signature to the final bound copies.

Declaration of presentation Standards

Include at this point a completed copy of the project submission page shown in workbook 10. Be warned, that if you tick this page and the relevant element is not found to be present, the work will be returned to you unmarked for correction.

Plagiarism Declaration

I confirm that the enclosed written work (including application code) is entirely my own except where explicitly stated otherwise. I declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions. I understand that wherever 6 or more consecutive words are extracted from a source they must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

Include as appropriate

9.7 General Grade Criteria

Workbook 14 gives general guidance as to how projects will be assessed. Workbook 14 also contains a table of the criteria used, although the emphasis given to various aspects may vary depending upon the nature of the work and should be explained to students in assessment specific criteria.

9.8 Project Examination Board Reflections

This is a discussion based on observations made on the marking forms and in the Examination Board regarding the quality of the submitted document as final Master's projects/dissertations. Most of these faults are due to shallow and sometimes very shallow thinking on the part of the project student and that is unacceptable at Master's level. The following points are to help both supervisors and students avoid known pitfalls and so produce a project document to a high standard.

9.8.1 Project Introduction – Study Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem definition – common deficiencies were no discussion or poor discussion of what problem was being addressed by the project. Without such a discussion it is almost impossible for a reader to get any grasp of what the project is about. In projects we want to see just ONE major problem theme not several so it often requires clear thinking to set it at the right level. (See workbook 6 section 6.2 and 6.5)

Target and Outcome – there is often considerable confusion over these two ideas. The target is about what might happen in the real world based on the project outcome but often students cannot distinguish what the project will generate and what might be done with that project outcome. As a simple example, students might say that the project outcome is "improved accuracy in data entry" when what they mean one supposes is that in their project they will design (say) a new training programme that will be used to get the real work target of improved accuracy.

Speculation and Personal Theory – students are encouraged to speculate about problem causes and solution routes to arrive at a personal theory about the problem theme and how it might best be resolved leading to a suggestion of an expected form project outcome. A reader expects to see some indication as to what form the project outcome will take and in addition some discussion of the form to at least show that it is likely to go some way to resolving the stated problem theme. Unfortunately, the form was often missing and even when the Research Design was consulted a typical reader could still not see what the project outcome was supposed to be. Here we want to see ONE major form outcome for each project. (See workbook 6 section 6.5).

Research Question - either missing, badly worded or multiple questions offered (sometimes all in one sentence). One common mistake was to ask a question in the form (or some equivalent) of "is it possible...." - the point is that in such questions the answer is almost always that it is possible so the research effort becomes pointless. (See workbook 6 section 6.7 and 6.9)

Process for Generating Primary Data - this is a key element in any project as it is essentially the main activity used to unlock the primary data. It is useful to discuss this process briefly in the introduction since that allows readers to link the problem theme and therefore see what data you are likely to be looking for.

9.8.2 Project Introduction – Engineering Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem Theme - there was either no discussion or poor discussion of what problem theme the application being built was supposed to resolve. When this happens it is almost impossible for a reader to get any grasp of what the project is really about. (See workbook 6 section 6.2 and 6.5)

Functional Description - many students could not provide a short functional description of the application they were going to build. The most common thing for students to do instead was to provide an overview of the application architecture. This is hopeless as architecturally almost all Engineering projects are the same in that they typically have a database and a webpage for example. This implies that students cannot or do not want to make a distinction between how an application is built and what its purpose is.

9.8.3 Aim and Objectives

In many cases these elements were missing altogether. In other cases one could barely link the aim to the Research Question or application description. However, of most concern was an apparent inability in many students to write a coherent and reasonable set of objectives. Not to be able to write an aim and more particularly objective is representative of a gross error and it should never occur in Master's level work.

Aim - usually composed in a reasonable way but there does seem to be an inclination in some students to cram everything into the aim as if they are some kind of superman. The recommendation is to have just ONE clear activity mentioned in the aim and that should be accompanied by a just one clear outcome for the aim. (See workbook 6 section 6.11, 6.11.1)

Number of Objectives - often there were far too many to be in any way practical for one student in the time available and often this was because they were all expressed at different levels of project resolution.

No Visible Outcome - there were many, many cases where the objectives had no visible outcome. Far too often we got phrases such as: "To understand...." or "To analyse...." without any object to the sentence so there was no outcome that was visible. Without a named outcome there is no way that the objectives can be seen to have been completed. (See workbook 6 section 6.11)

Not Project Bounded - there were many students who cited operational objectives as outcomes. For example it was common to see lines such as such things as "To improve the workflow in the invoicing section". Here is a case where such an outcome cannot be written into a document or be in practical terms viewed and so cannot be used in a project. Typically, unbounded objectives refer to something that might happen based on the project outcome after the actual project has been completed (See workbook 6 section 6.11)

Objectives as Requirements - very commonly but still rather worryingly, many students, on Engineering projects, seem to think that objectives are the same as application requirements. (See workbook 6 section 6.11)

Objectives as Benefits - less commonly but still rather worryingly, many students, on Engineering and study projects, seem to think that objectives are the same as benefits. For example, in a study project on CRM systems what one often finds in place of project objectives is a list of benefits of implementing CRM. Similarly, for Engineering projects we see objectives written as a set of benefits of using the application being built later on in the real world. (See workbook 6 section 6.11)

9.8.4 Literature Review

In research the literature review is regarded as being essentially preparation of the mind. It follows, that to be serious about this step one has to be evaluatory and reflective as you read and write. Ideally one needs a strong theme which is used to weave an expository and exploratory discourse that unites and builds one's understanding and ideas with what has been written by other authors on one's core topic area.

For projects a full literature review is only needed in the case of a study project. For Engineering all that is required is a thorough overview of the application area. So for example, if an application were about Insurance brokerage then all that is required is a description of what brokerage is but only to the level necessary to understand the requirements. With this aim in mind: (See workbook 5 but section 5.2 and 5.6 should be studied with care)

Structure - many reviews were poorly structured and one often felt that the students had just written down the material as it occurred to them without any thought as to a wider readership.

Theme - often there was no detectable theme connecting the various sections of the review narrative and a reader would therefore be forced to guess and see how all the various elements were connected.

Value Added - the most common flaw was to see a review that was entirely or almost entirely made up of quotations, paraphrases or summaries so that the 'hand' of the student was not detectable anywhere in the work. Such work is not evaluatory and gives no indication whatever that the student has learned anything of value or indeed anything at all. It is often the case that one feels the student has no notion of the literature being a driver that may mean they have to accept new knowledge, gain further experience, modify existing knowledge or even abandon what they thought was sacrosanct and sadly no belief that their own views and experiences are also important.

Citation Style - two things are evident here. Firstly, one finds that too often citations are limited to the Literature Review. Secondly, the actual style used is very poor and commonly we see the form (Burk, 1992 p45) placed at the end of a sentence or paragraph. This is not acceptable and can only mean the whole paragraph has been paraphrased. The ONLY correct use of this bracketed style is in a passing reference to a text. (See workbook 8)

Worthless Quotes/Paraphrases - it is unfortunately only too common to see an appeal to some text or other for information that tells you either common knowledge or makes an obvious observation and so the citation is worthless and is representative of weak scholarship and laziness where a student is just trying to add a citation because he knows that such things are desirable. For example, quoting an author who says that "Object Orientation is now routinely used in software construction" is representative of common knowledge or quoting an authors who "says change is inevitable in organisations" is something that one might regard as obvious.

9.8.5 Research Design

These were often far from satisfactory and often read like a joke delivered without the punch line. The students are taught that essentially there are two phases. The first phase is the process used to get primary data items that are formed into a collection. Once the collection phase is completed we move on to the second phase of processing where the collection of primary data is processed to get an answer in the form expected. Particular points are:

Research Phases - In many case students were unable to distinguish the processing needed to get a collection of primary data and processing of the collection of primary data to get an outcome. It is quite common to see these two phases ignored or become competed muddled leading to a poor research outcome because the student loses his/her focus and often appear to have no clear idea what they are doing. The phases are:

Phase 1 - a process or processes used to define and create a primary data collection. It typically has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the data and present the data.

Phase 2 - a process or processes used to manipulate the collection of primary data to get the form of answer expected.

No Outcome - often it seemed as if the student had no idea what form of outcome to expect so when one looked at the processing there was no sense that the primary data was being transformed into the required form of outcome.

Primary Data - many students seem to have only a vague notion of what primary data is and will often, very often, confuse or think that primary data is the same as the method of collection. This confusion is often evident with some students thinking that only questionnaire data could possibly be primary data.

Primary Data Definition - Primary Data is new data in the sense that it will not exist as a collection until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data collection is representative of some aspect of the area under investigation and can be processed to get a defined form of outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

For example, one student took the definition and then read through an accounting system manual for his company and extracted all the functions and claimed that was primary data because he was going to use it to define what an accounts package should have by way of functionality but seemed unable to see that the manual had effectively done that already. (See workbook 6 section 6.6)

Research Method Justification - often students could not distinguish between Research Method and Data Collection Protocols. Research Methods are frameworks such as Case Study, Experiment, Action Research and so on. Collection protocols are based on: interview, questionnaire, observation, role playing, seminars, focus groups and so on. The sorts of justifications used are of the form "I have chosen case study because Saunders (2005, p92) said case studies are good... This is hopeless and implies no real thought. Justification must be built from a sound understanding of a particular Research Question, its expected form of outcome and the Primary Data needs and at least an overview of which method is likely to be best in a given situation. (see Workbook 7)

Practicality - many plans were over-complicated with students trying to use multiple methods and then ending up with masses of data they had no idea what to do with. There is only limited time and so students should be encouraged to focus on just one Research Method although of course several protocols may be involved.

Data Collections - in many cases all an examiner was able to see were results but often one simply could not tell if any primary data collection was involved and the results just seemed to appear 'out of the air'. The marking guide is quite specific and projects must be clear about both processed data and raw primary data collections. Without this we cannot feel confident that students have done any actual research. Typically, the collection of primary data is placed in an appendix and might be in the form of a summary table of questionnaires results or summarised transcripts. Correspondingly, the processed primary data collection is expressed as charts, graphs, tables, reports and so on in the body of the project report.

Processing - this is one of the most disappointing elements. Processing is all about transforming your collection of primary data into the form of outcome expected. Far too often all we see is the processing of individual primary data items with no attempt or very weak attempts to really supply an answer to the Research Question in the form that was specified.

Location - there were quite a few projects where it was more or less impossible to see where the primary data came from and often this was accompanied by a very ordinary set of results that could have been written by almost anybody with a superficial knowledge of the subject area.

9.8.6 Research Results Processing

There were some very good examples but often this section was very routine and very disappointing.

Repeating - it was very common to see a chart for example, displayed and then underneath the student simply repeated the data that was in the chart in words. Such a practice is worthless. What any data related narrative is supposed to do is to tell the reader what the data means and what implication it might have - that is we expect to see some analysis and evaluation of the data in terms of the Research Question.

Focus - the focus of processing the primary data is to create a kind of transformation that generates from the collection of primary data the expected project outcome - unfortunately, this aspect was often absent. Typically in a survey for instance we have page after page of charts analysing individual data items but no attempt to sum it all up and reach a conclusion based around the Research Question.

9.8.7 Evaluation and Conclusions

These sections in a lot of student work are indistinguishable. The reason there are two sections with marks attached is because:

Evaluation - here one focuses specifically on the project outcome and research methods - that is we evaluate our product (outcome) and the methods used to generate it. Notice here this is NOT about generating the outcome that would have been done in the research processing section

Conclusions - here the attempt is made to say what it all means - that is trying to generalize the findings. So for example, suppose the outcome is about the use of Agent technology in eCommerce web sites then in conclusions one might try to say what a particular project outcome means for any eCommerce site or in fact any website. In a similar kind of way, if a particular application had been built we might try to say whether it might be applicable in other situations or whether some features of the design can be transferred to all applications of that type.

9.8.8 Ignorance of Project Marking Criteria

Many students show an almost complete disregard for the way a project is marked and so often automatically lose marks. Students must therefore carefully study the marking forms so that they know what components are regarded as essential to any project and therefore carry marks. (See workbook 11 or 12 as appropriate)

10. WORKBOOK 10 – FORM: PROJECT SUBMISSION

This form **must** be completed and included in your project submission. If you are unable to tick every box then your work is not ready for submission. If boxes are ticked and it is subsequently found that the relevant element is not present it will be taken as a deliberate attempt to falsify the record and regarded as a fail.

Project Word Count	Exclude appendices. If maximum is exceeded marks may be lost or the project rejected
	The report length is within the stated guidelines (15,000 words maximum excluding appendices)
	I have included all making elements indicated in workbook 11 Or 12 as appropriate and noted the marking guidance notes
	I have studied the guidance notes on common project faults found in section 9.6
	I have prepared two bound copies of all my project work including any separate appendices
	I understand that I may use one or both sides of the paper when printing the report.
	I have included a full contents list, table list and diagram list all numbered consistently
	I have used good quality A4 paper, normally in portrait orientation with a weight between of 80 and 100gsm.
	I have made sure that the pages are in the right order and none are missing
	I have used MS word .doc format
	I have formatted the front cover and title page as required and added the necessary plagiarism declaration.
	All my text is single line spaced at 6 lines per inch/25.4 mm.
	All my main text, including headings is in 12-point font (Arial Narrow is recommended)
	All my text in tables and diagrams is 10-point font (Arial Narrow is recommended)
	All main text is right and left justified
	No headings at whatever level are indented
	Headings are NOT followed by a blank line
	Headings are in the same font and size as the main text but are shown in bold type
	No numbered headings are orphaned (that is all heading must be followed by some text not immediately by another heading)
	I have used a single blank line to separate paragraphs
	All chapters and appendices are numbered sequentially (1, 2, 3,...)
	All subsections are numbered (2.1, 2.2,...) and none of my sections numbers exceed three levels (1.2.1, 1.2.3 ...)
	All my margins: (top, bottom, left and right) are 20mm
	Pages have centred footers in 10-pt Arial Narrow: Page 12 of 97 - J.J. Letto HEMIS No. 567543 Submission Date: 2004/05
	I have cited other people's work properly using the Harvard APA format
	I have included all citations in my list of references
	My abstract accurately summarises all of the report, not just parts of it
	All my chapters and appendices start on a new page
	I have included appendices, where appropriate, covering: project specification, Project Plan, Requirements document(s), design document, screen shots, source code, user documentation, test results, evaluation results, questionnaires, etc.
	My supervisor has read each chapter as the work progressed.
	My supervisor has read the whole report
	I understand that indented sentences can be used where appropriate but bullets are not recommended (see 9.3.1)
	I understand that page headers are not required
	I understand that each of my chapters should start with an introductory section that explains what the chapter is about
	I understand that each of my chapters should end with a summary and a helpful link to the next chapter
	I have fixed a copy in .doc format of the project document and any appendices on floppy/CD/DVD to my project submission
	All my primary data (including requirement data) is original to this study and collected by me for this specific project purpose
	Engineering Projects only - I have included an executable file of my application on an attached floppy/CD/DVD
	Engineering Projects only - Application Operating instruction are on the attached floppy/CD/DVD as well as in the appendix
	Engineering Projects only – In my application I have not used illegal copies of any software or included any software where there is an expiry date which may render the application inoperable in the future.
	Engineering Projects only - I understand that the copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If, and only if, this is not possible then I have included in my project a supervisor signed set of screen shots in the appendix confirming that he/she has viewed the application in action.
Signature of Student. Date.	

11. WORKBOOK 11 – FORM: STUDY PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

STUDY STYLE		Postgraduate Project Marking Form						STUDY STYLE	
Name of Student							HEMIS No.		
Brief Project Title							Total Mark	%	
Recommendation	If the mark awarded is a fail circle your opinion						Re-Work	New Topic	
Name: Supervisor									
Name: Marker									
Marker Status	Supervisor		Moderator		3 rd Marker		Re-Marker		
Project Unit	PJ.NCC								
Plagiarism	N	Y	Is PLAGIARISM or another unfair act is suspected						
External Examiner	N	Y	Refer to the External Examiner (if "Y" add comment in section G)						
Content	Y	N	Can you confirm that this project fulfils the criteria for the Unit						
References: See Workbook 11 for detailed marking guidelines and Workbook 14 for general expectation and grade criteria notes									
Section A - Marks for Planning and Preparation							Weight	Mark	
1.	Project specification, including project plan						5		
2.	Review of the topic area literature						15		
Sub-Total							20		
Section B - Marks for Project Introduction									
3.	Presenting problem and its exploration including the Research Question						5		
4.	Discussion of the project's scope, scale, aim and objectives						10		
Sub-Total							15		
Section C - Marks for Project Primary Data Research and Outcome Generation									
5.	Selection and justification of Research Method						5		
6.	Primary data collection plan including data specification						10		
7.	Primary data processing plan to get expected outcome						10		
8.	Presentation and discussion of the collection of Primary Data						10		
9.	Description and discussion of main project outcome						10		
Sub-Total							45		
Section D - Marks for Project Evaluation and Conclusions									
10.	Evaluation of the project outcome (Project Specific)						5		
11.	Evaluation of project practice (Project Specific)						5		
12.	Statement of conclusions and reflections (Project Generalisations)						10		
Sub-Total							20		
Section E – Qualitative Assessment matrix based on University Grade Criteria									
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words			
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless			
3.	Report structure	very poor	poor	satisfactory	good	excellent			
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report			
5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours			
6.	Project idea	trivial	easy	modest	challenging	Difficult			

7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Primary data collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Data processing	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
14.	Main project outcome	Worthless	obvious	useful	original	exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Study Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes found in Workbook 14.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.2 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the topic area literature

Reference: Workbook 5 section 5.2 and 5.6 in particular, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers and generally be focused on the central project topic. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and its exploration including the Research Question

Reference: Workbook 3 section 3.3 and 3.5.1, Workbook 6 sections 6.2, 6.6 and 6.7 and Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Research Question with a defined form of answer (project outcome). It is very common to see an expression of a problem as "my problem is to find a solution to..." or expressed in such a way that it is in effect a solution and such expressions are indicative of students who do not know what the problem is but nevertheless know what the solution is. Similarly, students who list multiple problems, have no Research Question (or a very poor one) and do not discuss the form of outcome expected are embarking upon projects where there is no clear focus and these typically fragment when it comes to the core research and one most often cannot find any clear project outcome later in the work. It is also useful at this stage if there is some indication of the Basic Activity for Generating Data (BAGeD) so that one can feel sure that the student is aware of what primary data they need in order to generate the intended outcome.

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.2 (example), Workbook 6 section 6.1 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition, expected form of outcome and Research Question all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Selection and justification of Research Method

Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful choice of Research Method focused on resolving the stated problem theme. In practice this implies a consideration of primary data needs, location of primary data and the collection protocols that might be used. Markers should guard against rationales that amount to saying that some text book or other said method X or Y was good for certain kinds of scenario – that is copies of generalisations about Research Methods found in books do not amount to a rational for a specific research situation. Furthermore, markers need to feel confident that the student understands the distinction between a Research Method and the collection protocols used within them.

6. Primary data collection plan including data specification

Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

This is a crucial stage in a research based project and markers must be confident that the plan is practical. A marker must look for a clear core activity represented by a statement about of BAGeD and that core activity should be surrounded by whatever other processes are needed to ensure reliable collection of the primary data. The whole primary data collection plan has four steps which must be visible in the project document: data definition, data location, data collection and how the whole collection of primary data is to be presented. Markers should also take care that the formation of a collection of primary data is not confused with the processing of it to get the stated project outcome.

7. Primary data processing plan and presentation of the expected outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for clear evidence that the student has taken the collection of primary data they obtained earlier in the project and now process that whole collection to get to a clear presentation of the project outcome. It is therefore important that markers can see what processes were applied to the collection of primary data to get the outcome – without this process visibility there is no evidence as to how the project outcome was actually obtained. Markers should be wary of processing plans that say such things as “I will look at the data” or “I will analyze the data” or “I will use SPSS” as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same data collection they could apply the same processes and get the same or at least a very similar outcome.
Markers should also be aware that very often students will often process individual data items – such as might be found on a questionnaire, but never get to a point where the stated project outcome is derived from the collection of data.
8. Presentation and discussion of the collection of Primary Data
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for visible signs of the collected primary data. The primary data collection is most often presented in tabular form in the appendix and might be displayed as graphs, charts, tables or diagrams in the main project document.
9. Expression and description of main project outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
The intended project outcome must be clearly visible – for example if the intended outcome is a model then that must be clearly shown in some acceptable form and be based on the processing plan outline in section 7. Markers must therefore take great care that the presentation of primary data and the processing of individual data items in the collection are not offered as a substitute for the student generating the intended project outcome.
Section D - Marks for Project Evaluation and Conclusions
10. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project outcome so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution (project outcome) or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project outcome. The section is not intended for vague thoughts about the topic but a considered evaluation of the project outcome when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
11. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate here. This section is important as this is where one expects to find some information on what the student has learned about the way they work and the tools they used. It is unfortunately often the case that students have very little idea about what they did apart from stating vague activities such as “look at”, “analyze” or “use SPSS” so without anything concrete to evaluate they resort to the routine and say “the survey process went very well” or “my case studies generated useful data” or else they simply ignore this form of evaluation altogether. Evaluation of project practice is difficult and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking ‘how did I do it’, ‘was it successful’ and ‘could I or should I on reflection have done it another way’. Additionally, one needs to be aware of any constraints involved, including time management and particular skills that might have impacted on the use of best possible practices.
12. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a project outcome was based on case studies and the outcome was a review of IT outsourcing in Hong Kong then here we might expect to see the student consider the outcome he obtained which refers to Hong Kong and then consider and discuss whether that outcome has wide applicability, for example, to China, South East Asia or even the world as part of a Global economy or is it just specific to that local situation. Essentially, one is asking what do the outcome ‘mean’ when set in a wider setting. It follows that the focus of awarding marks here is for project generalisations.
It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such as future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

12. WORKBOOK 12 – FORM: ENGINEERING PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

ENGINEERING STYLE		Postgraduate Project Marking Form				ENGINEERING STYLE	
Name of Student					HEMIS No.		
Brief Project Title					Total Mark	%	
Recommendation	If the mark awarded is a fail circle your opinion				Re-Work	New Topic	
Name: Supervisor							
Name: Marker							
Marker Status	Supervisor		Moderator		3 rd Marker		Re-Marker
Project Unit	PJ.PEA						
Plagiarism	N	Y	Is PLAGIARISM or another unfair act suspected				
External Examiner	N	Y	Refer project to the External Examiner (if "Y" complete section G)				
Content	Y	N	Can you confirm that this project fulfils the criteria for the Unit				
References: See Workbook 12 for detailed marking guidelines and Workbook 14 for general expectation and grade criteria notes							
Section A - Marks for Planning and Preparation					Weight	Mark	
1.	Project specification, including project plan				5		
2.	Review of the application/product area and its client/business setting				10		
Sub-Total					15		
Section B - Marks for Project Introduction							
3.	Presenting problem and outline proposal				5		
4.	Discussion of the project scope, scale, constraints, aim and objectives				10		
Sub-Total					15		
Section C - Marks for Project Primary Data Research and Outcome Generation							
5.	Detailed requirements collection plan based on proposal				5		
6.	Analysis of requirements: functional, performance, technical and usability				5		
7.	Presentation, analysis and discussion of the design				10		
8.	Discussion of build process and design implementation				10		
9.	Application testing process and results				5		
10.	Implementation plans				5		
11.	Attributes of the project artefact (e.g. quality, reliability, etc)				10		
Sub-Total					50		
Section D - Marks for Project Evaluation and Conclusions							
12.	Evaluation of project product against requirements (project Specific)				5		
13.	Evaluation of project practice (project specific)				5		
14.	Statement of conclusions and reflections (project generalisations)				10		
Sub-Total					20		
Section E – Qualitative Assessment matrix based on University Grade Criteria							
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words	
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless	
3.	Report structure	very poor	poor	satisfactory	good	Excellent	
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report	

5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours
6.	Project idea	trivial	easy	modest	challenging	difficult
7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Requirements Collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Design Expression	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
15.	Artefact Evaluation	worthless	obvious	useful	original	Exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Engineering Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.1 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the application/product area and its client/business setting

Reference: Workbook 5 section 5.2 and 5.6, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers. In Engineering projects the expectation is that the review will focus on the application area and be in enough detail to at least understand and gather the requirements. It is permitted to include technical material if they have a special or unusual significance to the application area but in so doing students must be aware that the routine inclusion of what at this level might be regarded as common knowledge in computing/IT will not attract any marks. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and Outline Proposal

Reference: Workbook 3 section 3.3 and 3.5.1 Workbook 6.2 and 6.5, Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Application Outline expressed as a functional description. It is very common to see an expression of a problem as "my problem is to find a solution to..." and this is indicative of students who do not know what the problem is but nevertheless know what the solution is. Students who list multiple problems, have no functional description (or a very poor one) are indicative of projects where there is no clear focus and these typically fragment when it comes to requirements gathering and often end in a very trivial application. Markers should be aware that students may avoid giving a functional description and instead offer a generic architectural one and this must be penalised as the student clearly does not know what function the application supplies

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.1 (example), Workbook 6 section 6.11, 6.9 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition and Application Outline all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Detailed requirements collection plan based on proposal

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful consideration of the Requirement Gathering process focused on obtaining sufficient information to build the intended application and resolve the stated problem theme. In practice this implies a consideration of application functions, location of requirements data and the collection protocols that might be used. Normally in research one would expect a rationale for the choice of Research Method but for Engineering projects it is taken for granted that the method is requirements gathering. Instead one should look for a clear focus on constructing a feasible and comprehensive requirements document based on the application outline. Furthermore, markers need to feel confident that the student understands the distinction between Requirement Gathering as a Research Method and the collection protocols used within it.

6. Analysis of requirements: functional, performance, technical and usability

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers must look for a clear Application Proposal and a requirements catalogue. Here one needs to see a discussion of the requirements to ensure they are credible (realistic), comprehensive, complete and stakeholders have been considered. One might also usefully consider the approach that was taken to gain them and whether they are of the form of strategic, tactical or operational.

7. Presentation, analysis and discussion of the design
Reference: Workbook 9 sections 9.6.5 and 9.6.6 and Workbook 7 section 7.9
Marks are awarded here for clear evidence that the student has taken the requirements obtained earlier in the project and processed them to get a suitable design. Therefore, markers must be able to see a clear link from requirements to design and where necessary observe how the requirements were processed. Markers should be wary of processing plans that say such things as "I will look at the requirements" or "I will analyze the requirements" as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same requirements they could apply the same processes and get the same or at least a very similar outcome.
8. Discussion of build process and design implementation
Reference: Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for a rational discussion as to what architecture, components, languages and tools and so on are needed to best implement the design. This discussion may also imply the various situation constraints have to be considered as well.
9. Application testing process and results
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers must look for evidences of a testing plan and a consideration of test results. Typically the plan and results are placed in the main project document in outline form with the details in an appendix. Often students will just discuss white or black box testing or regression testing or something similar but without any actual test plans or results – in such cases marks should not be awarded as these materials is considered common knowledge at this level – however brief references to it are permitted.
10. Implementation plans
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers should look for a comprehensive implementation plan – it need not be extensive or in minute detail but it should cover installation, user training, data conversion/loading, change over, user acceptance and hand-over.
11. Attributes of the project artefact (e.g. quality, reliability, etc)
Reference: none
The intended project application must be clearly visible and available to run directly from a disc or DVD. Markers are to award marks based on their perception of the general quality of the application if they were to put themselves in the place of a user. Assessment may then consider colour scheme, ease of use, operating instructions, presentation (does it look as if its finished), speed, etc.
Section D - Marks for Project Evaluation and Conclusions
12. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project application so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project application. The section is not intended for vague thoughts about the situation or application but a considered evaluation of the project application when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
13. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate. This is where one expects to find some information on what the student has learned, the way they work and the tools they used. It is often the case that students have very little idea what they did apart from being able to state vague activities such "look at" or "analyze" so without anything concrete to evaluate they resort to the routine and say "the survey process went very well" or "the UML modelling was straightforward" or else they simply ignore this form of evaluation. Evaluation of project practice is difficult because the student must ask searching questions related to process success and the notion of good and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way' or "what were my constraints".
14. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a an application was for eCommerce selling shoes it might be possible to ask what aspect of that application could be re-used to sell other product. It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

13. WORKBOOK 13 – FORM: PROJECT MARKING RECONCILIATION

The form shown below is included for reference only so that you can see how your project will be marked.

Project Mark Reconciliation Form		Final Agreed Mark (%)	
Name of Student			
Brief Project Title			
Name: Supervisor			
Name: Second Marker			
Name: 3rd Marker			
<p>Cause – in this box, describe, for each applicable section, why the marking disagreement occurred.</p> <p>Rationale – in this box, If a mark can be agreed, explain the rationale used to reach agreement. Please note that it is only necessary to agree the total mark for each section not individual category marks.</p> <p>Irreconcilable - If you cannot agree a mark leave rationale blank and it will be filled in by a third marker who will place a tick in the small square box.</p>

14. WORKBOOK 14 – SUPERVISION AND MARKING GENERAL GUIDANCE NOTES

1. **Presented Work** - Marker's are reminded that any marks awarded must be solely based on the assessment of work presented within the mark categories listed on the mark forms. It is not permitted to award marks for "hard worker" or "tried very hard" or "was a good student" or any similar observation as there are no relevant mark categories and this kind of criteria is almost impossible to evidence.

When an Engineering artefact is presented it should be viewed in action to ascertain the mark for "Attributes of the Project Artefact". The copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If this is not the case then markers must assume that there is no evidence for the application and set the mark accordingly.

2. **Word Count** – on the project submission form there is a space for a word count (excluding appendices) and if this is exceeded then it is indicative of a deliberate attempt to go beyond recommendations and you may therefore find that it leads to laboured descriptions or inclusion of irrelevant material in the project document and you should therefore mark accordingly.
3. **Structure** – mark categories do not necessarily represent chapters in a project document and so Marker's need to be aware that a particular project may be structured in a way that does not correspond to the sequence presented on the mark forms (though it is recommended to do this when possible). However, all the elements on the marking form must be visible in the work presented.

Although it is recommended that the mark form sequences be followed in the project document that does not mean that there has to be a chapter for each mark category. Students, therefore, should be encouraged to merge sections in order to produce a concise document. For example, it is perfectly possible and reasonable to merge the two evaluation sections and conclusions into one chapter as long as the relevant mark elements are still visible.

4. **Appropriateness** - any work presented must be within the prescribed subject area for the course. If a marker suspects that this is not the case then they should consult with the relevant course leader for clarification. In such accepted cases markers must regard the primary data and its processing as not being appropriate and mark with that in mind.
5. **Evidence** - the project report or appendix must contain sufficient evidence that the core project research work has been done (not the literature review). That is, in the case of study project a marker must be able to see the primary data collection appropriately presented (usually in an appendix). In the case of Engineering projects it must be possible to see a suitable requirement document or catalogue (possibly in the appendix). Once the primary data is visible then it must also be possible to see how that data was transformed into the intended project outcome.
6. **Literature Support** - when marking Literature Reviews their content must be seen to be focused on the topic area and address clearly the associated problem theme without any irrelevant material with the intention of offering a concise discourse that is focused, relevant, authored, measured, evaluatory and expressed as a dialogue. (see section 5.1)
7. **Grade tables** - markers must be aware of the criteria associated with awarding a given overall mark as they may be required to justify it to the UAB in terms of the criteria stated in the table shown below.
8. **Process** – when marking it is important that the process used to get an outcome by the student is visible in the project document. In practice this means that it is possible to perform the following trace: presenting problem, discussion of how problem might be resolved, suggested form of project outcome, research design and execution, generation of stated outcome, evaluation and conclusions – viz:

Engineering – typically, the process starts with a business related or technical problem theme leading to a research plan for the collection and discussion of requirements and their transformation into a suitable design and associated architecture. From this there should follow a build, implement and testing process with the whole project completed with suitable project specific evaluations and conclusions containing generalisations.

Study – typically, the process starts with a business or strategic IT related problem theme leading to a research plan for the collection and discussion of primary data and its transformation into an outcome that would resolve or go some way to resolving the stated problem theme. The whole

project is then completed with suitable project specific evaluations and conclusions containing generalisations.

Marks	Master's Level Grade Criteria
70 – 100	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Excellent work - able to express an original reasoned argument in a lucid manner by reviewing & critiquing a wide range of material. Original, critical thinking based on outstanding insight, knowledge & understanding of material. Material contributes to current understanding & is of potentially publishable quality in terms of presentation and content ▪ Wide reaching research showing breadth & depth of sources
60 – 69	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Clear, balanced coherent critical & rigorous analysis of the subject matter. Detailed understanding of knowledge & theory expressed with clarity ▪ Extensive use of relevant & current literature to view topic in perspective, analyse context & develop new explanations and theories
50 – 59	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Detailed review and grasp of pertinent issues & a critical contextual overview of the literature. Thorough knowledge of theory and methods & uses this to underpin arguments and conclusions ▪ Confidence in understanding and using literature
40 – 49	<ul style="list-style-type: none"> ▪ Demonstrates grasp of key concepts & an ability to develop & support an argument in a predominately descriptive way with valid conclusions draw from the research ▪ Familiarity with key literature which is cited and presented according to convention ▪ Logical & clear structure, well-organised with good use of language and supporting material
0 – 39	<p>FAIL – Some knowledge of relevant concepts & literature but significant gaps in understanding and/or knowledge. Little attempt at evaluation, conclusions vague, ambiguous & not based on researched material. Limited or inappropriate research. Deficits in length, structure, presentation &/or prose.</p>

15. WORKBOOK 15 – FORM: UNIT FEEDBACK REPORT

This form may be used by you to feedback to the University your experiences in the courses. It is normally sent to your tutor at the end of the course.

Unit Level Feedback – Delivery Evaluation for Online Units										FF.2.3		Page 1 of 1	
This student feedback questionnaire is intended to help students provide constructive feedback to the unit lecturer.													
Student Name (Optional)										Cohort			
Unit Name													
Lecturer													
Q	 Good					Place a ✓ to rate each factor from strongly disagree to strongly agree in one of the 5 boxes							
1						Chat sessions started promptly.							
2						Char sessions were structured usefully for learning.							
3						Chat content helped my understanding							
4						Chat Tutor handled student questions sympathetically							
5						Chat Tutor used helpful examples where necessary							
6						Chat Tutor answered session questions in a helpful manner.							
7						Chat sessions stimulated me to think beyond the material delivered.							
8						Chat topics were often related to real-world situations.							
9						Chat Tutor encouraged students to participate during the session.							
10						The Tutor was expert in the subject area.							
11						The written notes provided were helpful to my learning.							
12						The study pack Workbooks were helpful in my assessment preparation.							
13						The 5 milestone tests helped me to confirm my knowledge.							
14						Tutor responded in a timely fashion to discussion board questions.							
15						Tutor responded in a timely to my email communications.							
16						Tutor was sensitive to the problems of individual students.							
17						The assessed work stimulated me to think deeply about my project.							
18						Feedback on my progress was available.							
19						The topic approval process helped me think clearly about my project.							
20						Written assignment specifications were clear.							
						For Official Use Only							
General Comments:													

I. Title: Document Management Strategies

II. Background: Managing documents is important for any organization. Every company has its own document storage and retrieval systems. A document management system (DMS) is a set of computer programs to track and store electronic documents and images. Document management systems basically provide storage, security, metadata, versioning as well as indexing and retrieval capabilities. DMS is increasingly being used in UAE both in private as well as government sector. e-Tawasul-Document Management system of UAE e-government is one such example.

III. Presenting Problem Definition: Despite being time, space consuming and expensive to maintain, use of traditional DMS still persists. Adopting proper document management strategy is therefore very important. DMS has far more potential than merely reducing paper work. Organizations in UAE need proper DMS strategies to efficiently track and store documents.

III. Real World Target: Inform UAE companies about the advantages of an efficient DMS. The reduced time for data retrieval, storage and security can help companies reduce storage, distribution and people costs.

IV. Research Questions: What are the bottlenecks in present DMS in UAE? How can they be overcome? How can they be optimized to reduce storage, distribution and people costs?

V. Personal Theory: DMS is very important for an organization. I believe that DMS can significantly help UAE organizations in storage, retrieval, filing, security, archival, retention, distribution, workflow and creation of documents. DMS can help UAE companies to reduce storage, distribution and people costs.

VI. Intended Project Outcome: The project aims to come up with strategies for efficient document management. It will analyze the reasons for Data Management bottlenecks in UAE organizations and suggest strategies and best practices to overcome them. Proper approach for migrating from a traditional to a modern DMS will also be laid down.

VII. Strategic IT Value: DMS not only helps in cost reduction but also in increased productivity of the employees. UAE Organizations can achieve substantial business benefits like improved customer service, reduced order-processing time, faster internal approvals, improved AR and collections, reduced processing errors and increased business process control by implementing modern DMS strategies.

VIII. Design for Collecting Primary Data: I will analyze bottlenecks and complications in document management processes. It will involve analyzing present document management processes in UAE organizations. I will interview key people in the organizations for collecting primary data.

IX. Design for Processing Primary Data: I will use the collected primary data to analyze reasons behind DMS bottlenecks. I will also evaluate successful approaches adopted in organizations to tackle them. I will then suggest effective strategies for document management.

Project Proposal –

1. Title –Document Management strategies (78)

2. Background-

Document management strategy is intrinsically linked to the development, evolution and optimization of its operating processes in many organizations. Document Management for the Enterprise simplifies the principles of document engineering and management. Document management is one tool among several collaborative computing tools necessary for users to manage information.

3. Presenting market potential –

The company's massive scope of operations and their geographical spread meant that large volumes of data of varied genre were being created at dispersed locations. So now it is essential for organizations to organize contents/ documents in a way that optimized its usefulness to multiple users across the organization. Document management solution should reduce cost of ownership for both purchase and administration by integrating document management into an existing collaborative/information management solution.

4. Real-world target-

Convince organization to implement document management strategies which will enable them to access information dispersed throughout the organization, whether local or global and effectively provides quick, easy access to information regardless of the source.

5. Research question –

To develop and agree whole-life document management strategy and implement a solution that will cover both internal and external procedures with standards for processes and document.

6. Personal theory –

To overcome information overload by giving users the ability to organize, filter, prioritize and manage a variety of data types we need to convince enterprises to implement document Management strategies in business processes.

7. Intended project outcome –

My expected outcome will be set of benefits and explanation of in- depth features and functionality of data management strategies in maintaining huge data bases in enterprises.

8. Strategic IT value –

By Uniting the various repositories for files and documents organization can keep track of their data bases by date, process, type, status and priority wise to efficiently maintain their business processes. Document management solution handles documents by electronically storing, organizing, indexing and filing. They can be retrieved when required, without any loss of time. The cost of miss management of documents is too high.

9. Design for collecting data –

Scope of this study to know the life cycle management of documents to draw what kind of benefits firms can make by implementing a document management system in current business processes.

10. Design for processing primary data -

Study the behavior and attitudes of different industries with the help of cases and tools which they have implemented and leveraging the strengths in best possible means to improve their customer centricity in low cost by using document management strategies.

Project Proposal –

1. Title – Impact of IT on international supply chain management (36)

2. Background-

Supply chain management (SCM) is the practice of coordinating the design, procurement, and flow of goods, services, information and finances, from raw material to parts supplier, to manufacturer to distributor, to retailer to consumer. This process includes product design, order generation, order taking, information feedback and the efficient and timely delivery of goods and services.

3. Presenting market potential –

Information technology and the Internet have revolutionized the way companies do business. They have changed the way organizations operate by enabling the re-engineering of sourcing, production and logistics processes

4. Real-world target-

The classic objective of logistics is to be able to have the right products in the right quantities (at the right place) at the right moment at minimal cost. Increased competition, ever expanding product variety, and more demanding consumers require more efficient supply chains

5. Research question –

How to effectively manage the supply chain using information technology is a topic of discussion in all levels of management, regardless of industries?

6. Personal theory –

I think IT in SCM presents both challenges and opportunities for supply chain managers because of its ability to collapse time and distance. Keeping this in mind firm needs to be understand the implication of supply chain management implementation in their transaction processes.

7. Intended project outcome –

My expected outcome will be a set of examples probing the utilization of IT in supporting supply chain management by developing a set of metrics to monitor the supply chain so that it is efficient, costs less and delivers high quality and value to customers.

8. Strategic IT value –

This research study provides a realistic portrayal of a key benefit of information technologies in supporting buyer-seller relationships. Using IT in SCM companies can follow a practice known as just-in-time manufacturing, and it allows companies to reduce the amount of inventory that they keep. This can cut costs substantially, since they no longer required to produce and store excess goods.

9. Design for collecting data –

I will collect the sample data from companies willing to share openly their results which have achieved using Information technology in their supply chain management.

10. Design for processing primary data –

On data collection an analysis will be done which will include the process description and the technology used. The in-depth benefits will be identified on the basis of qualitative and quantitative data available.

Project Proposal –

1. Title – IT and Logistics Management (31)

2. Background-

Logistics Management is that part of Supply Chain Management that plans, implements, and controls the efficient, effective forward and reverse flow and storage of goods, services and related information between the point of origin and the point of consumption in order to meet customers' requirements

Presenting market potential –

Information and communications technologies are revolutionizing the scope and scale of logistic management. Online data exchange is transforming business practices, allowing managers to capture and track complex data more effectively. Orders and various products related to that order can easily be traced. It is also possible to exchange information among entities within the value chain, thus greatly improving customer-provider relationships.

3. Real-world target-

Once Information technology gets involved in Logistic management, a number of benefits can be noticed like electronic trading of goods and services, online tracking of goods, carrying out banking transactions and processes electronically and electronic submission of customs documentations and declarations and payment of duties and taxes electronically.

4. Research question –

How organizations can fully utilize their IT capabilities to make their logistic management activities stronger in presence of constraints like lack of coordination between supplier or buyer etc.

5. Personal theory –

Presence of IT has taken over routine duties, which it performs much more efficiently and accurately than human beings, thereby providing individuals and teams with ample time for engagement in value creation.

6. Intended project outcome –

My project outcome will answer some of your questions like how will the widespread use of IT change the ways people work together? Improvements in IT have significantly changed how information can be processed and communicated, which in turn has led to increased interest in the study of interdependencies between organizations.

8. Strategic IT value –

Once organization starts using IT with Logistic management it will help them in enabling the move from centralized to decentralized management without any loss of information at any level; other advantages include speed/timely delivery, reliability, cost saving, security, etc.

9. Design for collecting data –

My procedure will explain the case studies in which IT has made performed a significant role in maintaining material management, ease the transaction process and shown transparency at every step to make product process flow effective.

10. Design for processing primary data -

After collecting data I will classify my study in to industries for determining the quality and competitive advantage of organizations by highlighting role of IT in logistic management.

Project Proposal –

1. Title – Business Advantages of Sarbanes Oxley compliance (181)

2. Background-

Sarbanes-Oxley is a comprehensive law designed to prevent corporate crime, and it fundamentally changes the business environment. Sarbanes-Oxley requires annual assessments of the effectiveness of whatever internal controls the corporation has established. The Act turns automatic document destruction into a process that must be monitored, justified, and carefully administered.

3. Presenting market potential –

Sarbanes-Oxley is about improving transparency and accountability in business processes and corporate accounting to restore confidence in public markets. It regulates processes and business practices. Sarbanes-Oxley compliance provides public companies with a golden opportunity to enhance the quality of their financial operations. Companies can achieve a return on compliance spending by using SOX as a lever to improve business processes- processes mapped as part of their SOX documentation.

4. Real-world target-

Educate and convince organization to achieve process improvements that will increase business efficiencies and competitive advantage after implanting SOA in their business process

5. Research question –

How Sarbanes-Oxley Compliance describes the new realities facing firms, spells out the steps needed to meet the new requirements, and offers techniques for evaluation and continuous self-assessment that will become a blueprint for survival in this turbulent business environment.

6. Personal theory –

Sarbanes-Oxley compliance has forced and is continuing to force companies to reengineer their business processes, which can improve overall enterprise risk management and business performance and therefore create enormous productivity gains

7. Intended project outcome –

My outcome will tell you the steps that leading companies are taking to manage their Sarbanes-Oxley compliance more efficiently and cost-effectively and also explore strategies that use workforce-related data as a means to increase the visibility and transparency of financial information and at the same time gain more control.

8. Strategic IT value –

The outcome after implementing Sarbanes-Oxley act in business will let organization to achieve high performance with low risk involvement and high level of transparency. Organizations can benefit from automated controls such as identity and access management, which reduce the effort, time and cost associated with audits.

9. Design for collecting data –

My process will evaluate cases where Sarbanes-Oxley act compliance has shown high level of commitment in making business processes transparent and profitable.

10. Design for processing primary data -

After collecting data I will classify my study in to industries for determining the quality and competitive advantage of organizations by implementing Sarbanes-Oxley act.

4. Real-World Target - Increase the effectiveness of implementing Sarbanes Oxley Compliance.

Tutor Comment - There is a hint of something good here but it does unfortunately sound as if it all about implementation and nothing about compliance. Now the student may have meant by implementation to include the idea that what we really want is secure compliance but in this case I don't think that entered his mind because he is fixated on this solution to the compliance problem. One should also be aware that observing or measuring "effectiveness" is not easy to do.

5. Research Question - How to implement Sarbanes Oxley Compliance with IT/IS automation in an effective way?

Tutor Comment - This is very poor indeed as in English it is very unlikely that anyone will understand this as even being a question at all. This is deplorable as the notes are explicit on this kind of error and so clearly the student has not bothered to study the relevant workbook section with any kind of care even though he has confirmed that he has. This is reprehensible behaviour, compounded by the fact that even though there was an exercise on this, that cannot have been attempted either.

Research Questions have 5 features: (SPITS) spotlight, problem, interrogative, target and suggestion. SO what can we find her if we are generous and see it as a question:

Spotlight - try to put the spotlight on where the primary data or information needed to answer the question might help come from.

Problem - this is about focusing on a single problem, so try to be as concise as you can.

Interrogative - what is your key interrogative word (how, why, what etc). You should note that some interrogatives need to use two words if a proper question is to be formed. For example, "how" on its own will not normally make a question but when you say "how can.." it is clearly a question.

Target - think about what will happen in the real world if you can resolve the problem. For example, it might be your target was to gain efficiency improvements, provide or enable better communication, increased accuracy and so on. It is also possible, but usually unwise, to state the target negatively if this makes the wording of the question more natural and you will see examples of this in section 6.7.

Suggestion - here one thinks about the problem theme and simply asks what sort of answer and what form it might take. So sort of answer might be yes/no, an explanation, an exploration, a description and these sorts of answer might be expressed at the end of the project as a report, a model, a list and so on.

6. Intended Project Outcome - It is anticipated that this report will produce a clear implementation strategies in an effective way for Sarbanes Oxley Compliance. Some companies' example will be used for data processing and analysis.

Tutor Comment - recall that this student's Research Question asked "how" so we might reasonably have been expected to find the outcome as a process or procedure of some kind. Here we now find it's a set of strategies and I cannot see a strategy as defining a process so this looks inconsistent to me and I think he is guessing that this sounds convincing but has not thought it out and in my view has no idea what a strategy actually is. In the last sentence the student seems to be saying that in fact he will copy the strategies from other companies and that is effective plagiarism.

So if we are generous here we would say that he is going to collect a set of strategies from other companies and then he is going to look through them is some way to construct another set of strategies for a particular company. I don't like this because he is not extracting any primary data from the presenting problem situation at all and is assuming that company situations are all similar but of course if that is the case we might as well use the collected strategies without any processing at all.

7. Design for Collecting Primary Data - Basic Activity for Generating Data (BAGeD) will be used. My process is to draw up a list for all known types of automating Sarbanes Oxley Compliance operation products with companies' selection for future analysis.

Tutor Comment - there is a hint of a BAGeD but obviously by the way he refers to it in the first sentence he has no idea what it means and is just trying to cover up that fact. The second sentence is more useful where he suggests that the Basic Activity turns the spotlight onto known products (well we cannot list

7. Design for Collecting Primary Data - Basic Activity for Generating Data (BAGeD) will be used. My process is to draw up a list for all known types of automating Sarbanes Oxley Compliance operation products with companies' selection for future analysis.

8. Design for Processing Primary Data - As long as I have the primary data, I will separate them into different types since they comply different code components of Sarbanes Oxley Compliance. To successfully create my intended outcome, I will construct illustration strategies and produce report on efficiency on different kind of products and their compatibility for the companies.

Student Example 3

1. Project Title - The wireless technology how influences the development on video game industry

2. Project Setting - Nowadays, the wireless technology application is most popular, due to the wireless technology development become mature, almost everyone uses in the home or at work place. Now the wireless technology starts apply on the entertainment especially on video game industry, whether a hardware console manufacturers or a software developer would like to utilize the wireless technology to enhance connectivity that for attempting present the high speed and many-to-many video gaming environment, also changes the game mode and control method.

3. Presenting Problem Definition - In the market, some hardware console has applied the wireless technology currently, whether is the Wi-Fi or IR (infra red). However, these functions are used more frequently for Internet browsing or data sharing temporally that can't satisfy the video game player. The video game player would like to apply the wireless technology to play a game anywhere and make the many-to-many environment that allows the video game player and their competitors play the game together, even change the game control methods

4. Real-world Target - Through apply the wireless technology, the hardware console enhance supporting on high speed wireless connection and game control method. The software developer develops the many-to-many video gaming environment that allows the game player with this platform to play the game with their competitors which enlarge the customer base

5. Research Question - Wireless technology how influences the development on the video game industry which include the trend of hardware console manufacturers, trend of software developer and the player of video games

6. Intended Project Outcome - Apply the wireless technology on the video game industry. It will make another industry growth. The hardware console manufacturers and software developer will change the traditional concept in video game industry that affect the video game mode of video game player especially focus on the mobile gaming and online gaming market

7. Design for Collecting Primary Data - The BAGeD will be to identify the wireless technology how to influences the development on video game industry. My process will prepare a set of the question which including the hardware console manufacturers, the software developer and the video game player. The questionnaire is made accordingly and it will send via different channel, such as e-mail and forum for collect the meaningful data about the project title.

8. Design for Processing primary Data - One the primary data is collected from different channel. I will classify the data in threes main categories that are hardware console, software developer and video game player, also will prepare an illustration and strategy accordingly.

Appendix E – Sample, letter of support format

All projects require a letter of support to confirm that the data being collected is new. The letter must:

1. Be on headed note paper and signed by a person in authority within the Company/College. Their name must be also stated in full as well as their status or position.
2. The letter(s) is to be scanned in colour and the image attached to the submitted Assessment 1a Part 3.
3. A typical wording would be as follows. However, the company/college may choose their own wording or add extra sections as they please.

Company Format

This format is to be used when your research project is based on gathering data from an organisation. This format is the norm. If you are using more than one organisation then you must supply a letter from each one unless you are using a large number, in which case you must use the College format.

Dear Sir,

My name
Re. Mr Victor Chow. Project: Planar Similarity – A new Synthetic Software Metric

I confirm that the named student is carrying out research at the above named company and I further understand that this research is part of the assessment to gain a Master's qualification. The work proposed by this student is new and I can confirm he is not using any pre-existing data.

The student has explained that the University will regard all data and results as confidential and it will only be made available to University tutors and the External Examiner and will not be published in any public forum without our full written company consent.

Any enquiries relating to this letter should be addressed to Dr Chin Wong of 0986 34571 or via email at chin.wong@ace.org.

Yours Sincerely

Manager
Dr Chin Wong
Technical Director (New Products Division)

To: Dr Tineke Fitch

fred.gardick@gmail.com

tineke.fitch@port.ac.uk

PgD College Format

This is the format to be used when your research project is based on gathering data from where there is no obvious organisation involved. This is expected to be the exception rather than the norm.

Dear Sir,

Re. Mr Victor Chow. Project: Planar Similarity – A new Synthetic Software Metric

I confirm that the named student is carrying out research on the above named topic and I further understand that this research is part of the assessment to gain a Master's qualification.

I have checked the student record and questioned him about previous project work and I am assured that the work proposed by this student is new and does not use existing data and that this is representative of a new project idea.

The student has explained that the University will regard all data and results as confidential and it will only be made available to University tutors and the External Examiner and will not be published in any public forum.

Any enquiries relating to this letter should be addressed to Dr Philip Ling of 0986 34571 or via email at p.link@ace.uae.org.

Yours Sincerely

Dr Phillip Ling
Director of Studies

Integrated Systems

1	Attempting to integrate all systems in a company is unwise
2	Highly Integrated systems such as SAP increases worker commitment
3	Highly Integrated systems such as SAP increases worker stress
4	IT/Computing standardization of systems and the impact on business success
5	IT/Computing standardization of systems and the impact on business policy
6	Legacy Data and BI Tools sets
7	Leveraging Data and BI tools sets
8	Lightweight Enterprise Architectures - a way forward in cost control
9	Microsoft Dynamics – A challenge to SAP and Oracle
10	Migration Practices for Legacy Systems and Business Planning
11	Modern HRM systems have had a major impact on recruitment and retention of staff in large organizations.
12	Service-Oriented Architectures (SOA) – A new breed of Applications
13	Taking a cross-organisational approach to IT
14	The impact of IT on global manufacturers

General IT Products

1	Blog Monitoring – A possible business Strategy?
2	Bloggging – A possible business Strategy
3	Bloggging – Is gagging bad for business
4	Business implications of the Web Bases OS
5	Implementation and training for BizTalk or Sharepoint Portal Server or Content Management Server etc
6	IT Collaboration Tools and Business Success (email, Intranets, shared files, desktops, user profiles etc)
7	Microsoft Office Business Scorecard Manager – A modern Management tool
8	Modern Software Development and its role is helping the disabled IT professionals
9	Optimisation of IT services (eg HP OpenView)
10	Search Engines and business Efficiency
11	The next wave – Computer Systems that never Fail
12	The next wave – computers that think like humans
13	The role of BizTalk or Sharepoint Portal Server or Content Management Server in business success
14	Voice activated input system and their efficiency in business situations (such as Via Voice)
15	Voice activated systems – a productivity tool
16	Web 2 a new model of usage
17	Web based desktop tools and their use in business
18	Web Services – The future for distributed systems (.NET and J2EE etc)

Document Management

1	Document Management and support for Critical Business processes
2	Document Management Strategies
3	eBooks and Readers – their use by business
4	Electronic Documents and Record Management
5	Strategic Issues in Document and Information Management

Theoretical Issues

1	IS needs must be matched to value in that IS systems can only be successful if there is a causal link to business success.
2	IT Application and Organisational Change
3	IT needs to be at the heart of all business plans
4	IT reporting functions and Business Instinct
5	Knowledge Management and its place IT planning/procurement/success etc
6	Mobile Technology Offers Staff a more satisfying work-life balance
7	Results oriented approach to the UI (instead of command-oriented – see 2006 MS office 12)

4	IT and Business Risk
5	IT Infrastructure and Business Continuity Planning
6	Managing business Continuity planning with highly integrated systems
7	Possible cost-based processes as critical management tools with regard to IT

Please remember I don't want a copy of your job specification. I don't need to be impressed by who you are, I don't need to be amazed by all the things you know and your qualifications, I am not looking to employ you, I am not awarding any marks, I am not giving out any prizes I just need to feel I concisely and precisely know who you are, what you do and where your MSc project interests lie.

Appendix B – Submission Check List for Assessment 1a Part 3

This form must be included as an appendix to the submission of part 3 of this assessment and it is intended to show you that you have correctly formatted work and included all that is needed.

If you are unable to tick every box then your work is not ready for submission. If boxes are ticked and it is subsequently found that the relevant element is not present it will be taken as a deliberate attempt by you to falsify the record and the work and 2 marks will be deducted for every case where a ticked is used but found to be not a true statement.

Word Count		The maximum permitted word count is 3,000 excluding project plan and reference list.
1.		I understand that if ANY item ticked is found to be untrue 2 marks will be deducted.
2.		I have written down the word count and it does not exceed the permitted value
3.		I have include a short literature review as required
4.		I have included a specification as required using the latest format
5.		I have used the correct margins of 2cm top, bottom, right and left
6.		The work presented is in A4, MS .doc format using portrait orientation (project plan may be in landscape)
7.		I have used Arial narrow font at 12pt size except in the project plan, reading list and page footer where I have used 10pt.
8.		I have used a line spacing of 6 lines/inch
9.		Pages have centred footers in the form - Page 1 of 5 - J.J. Letto HEMIS No. 567543 Submission Date: 2004/05
10.		I have not used page headers
11.		All main text is right and left justified
12.		Headings are NOT followed by a blank line
13.		Headings are in the same font as the main text but are shown in bold
14.		I have used a blank line to separate paragraphs
15.		I have not numbered any paragraphs or sections
16.		I understand that indented sentences can be used where appropriate but bullets are not to be used
17.		The first page uses the assessment heading lines shown on the specification sample in workbook 3 section 3.5.2
18.		I have used the correct format for a specification as found in the sample contained in workbook 3 section 3.5.2
19.		The submission file is named with only my HEMIS No. (if anything else is added your file will be automatically deleted)
20.		I have sent my personal profile to the Research Methods tutor
21.		I have sent my induction checklist to the Research Methods tutor
22.		I have looked up and studied ALL the Workbook references mentioned in this assessment
23.		I have included all citation sources used in my work in my list of references
24.		My short Literature Review is not be made up of just quotes and paraphrase but is an evaluative dialogue
25.		I have cited other people's work properly using the Harvard APA format
26.		I have included a references list of at least 10 literature sources
27.		My reference list contains no more than thee books covering Research Methods and Statistics
28.		I have only used the citation form (Briggs 1999) for passing references to texts
29.		I have included at least 3 sources covering the core topic area of this research
30.		In the reference list no more that 20% are internet sources
31.		The specification includes a plan to get original data (primary data) and I do not have that data already
32.		I have ensured that the primary data collected can be used to generate a Strategic Business IT outcome of some kind.
33.		My data processing design will generate the stated outcome form and the plan is clear enough to be executed by anyone
34.		The project has a significant learning potential in the IT/computing field
35.		I understand for this degree only the project style known as "Study" is allowed.
36.		I have attached a scanned letter of support from the organization where I intend to collect data (see appendix E)
37.		Plagiarism Declaration - I confirm that the enclosed written work is entirely my own except where explicitly stated otherwise. I further declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions. I further understand that wherever 6 or more consecutive words are extracted from a source they must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

you have not used the format shown in the Workbook Pack Release 3.2c the proposal will not be assessed and you will have to do it again.

Checklist - The formatting details are set out in the checklist found in appendix B which must be included with your submission and is a declaration by you that the work is ready to submit.

Part 3: Section 1 – Literature Review worth up to 20 marks

References - see Workbook 4, Workbook 5 especially Section 5.1, 5.2 and 5.7 and Workbook 9 Section 9.6.5.

Process - In order to carry out the project work you must have a fully prepared mind and that preparation is carried out using a thorough Literature Review. However, in this section we only expect a short review so that the University can assess your commitment, scholarly assets and preparedness for moving to the project phase. It is hard to be precise here but a short review of between about 800 and 1,000 words is normally adequate.

Part 3: Section 2 – MSc Project Specification up to 65 marks

References - see Workbook 3 section 3.1, 3.3 and 3.5.2

Process - To write up this work use the study project style headings and format located at the above references. You are advised that the tutor is not permitted to read your specification before submission as it must be seen to be entirely your own work since it is a formal assessment. However, the tutor will be happy to accept specific questions or discuss aspects of your work related to the various research elements and principles. It is hard to be precise here but good specifications are typically about 1,500 to 2,000 words.

Warning - to be able to move to the project stage you **MUST** normally achieve a mark of at least 40 (about 65%) in the project specification.

It is therefore possible, that you could pass the Research Methods unit but be judged, because of a poor specification, as not yet ready to begin the project itself. If this happens to you will be allowed to just submit the project specification again.

Purpose - The purpose of this part of the work is to gain approval for a project idea from the University by writing a short MSc project proposal. This is assessed work so you will only be allowed one attempt to gain the full range of marks. If for whatever reason your idea is rejected you may make another attempt as soon as you can but in such a case the maximum mark you can attain for this work is 4 out of the available 10.

Topic Area Selection - Appendix D contains a list of topic idea, they do not have to be selected they are there to show you the range of possibilities in writing a project proposal - there is an example proposal in appendix A to this document. But recall, the key element is that you must be able to collect primary data and it must be possible to regard the topic as Strategic Business IT.

Study References - The following Workbook and section references are to the Student Workbook Pack Release 3.2c.

Encouragement - You **MUST** expect to go backwards and forwards many times over all the headings in the proposal until you have a concise, coherent and lucid proposal that is your very best work.

Submission - When your proposal is ready use WebCT email to send it to the Research Methods tutor in a text only (no formatting, no diagrams, no tables etc) message – it must **NOT** be sent as an attachment. You are advised to seek approval as soon as possible but it would be very unwise to try to do it until after the first two formal subject area chat sessions.

Supervision - If your project proposal is approved then you will be allocated a supervisor within about three weeks of the cut off date. It is very important therefore that you make sure the submission is sound because if it is not satisfactory you will not get a supervisor and you will have to wait until the results of the specification are available several weeks later. The standard is very high so unless you study with care all the references and produce your very best work you will not be allocated a supervisor.

Format and Word Limit - Write the proposal using the headings shown below but you must not exceed 500 words (including the headings and declaration). If the word limit is exceeded, any headings are missing, any headings are altered, the sequence of headings changed or any headings added the proposal will not be assessed and you will have to do it again and the marks capped at 4 out of the available 10.

All work is submitted with a declaration and this must be offered honestly. If you cannot offer the declaration then your work is not ready for submission. If the tutor feels, based on the quality of your submission, that you have not adequately prepared for this work by studying the references he will reject the work and tell you that in his opinion you have made a declaration with intent to deceive.

Project Proposal (Word Count =)

Declaration – I <student name> confirm that I have carefully studied all the Workbook references in constructing this proposal and that what is described here is a new work and is not copied from any source.

1. Title – Construct a title in not more than 100 characters, workbook 6 section 6.13 will help you do this.

2. Problem Setting – Give an overview of your problem setting as background to show how you identified the problem theme.

3. Presenting Problem Definition – define a single significant IT or IT related problem that you are trying to solve. See Workbook 6 section 6.5 and 6.9.

4. Real-World Target – state what real world benefit or effect there will be if the stated problem can be resolved or partially resolved. See Workbook 6 section 6.3 and see Workbook 3 Section 3.3 and 3.5.2.

5. Research Question – write a question you want to ask as a way of encapsulating the quest to resolve your problem theme with your stated target. Use Workbook 6 sections 6.7 and 6.9.

6. Intended Project Outcome – what is the form and content of your expected MSc project outcome that arises naturally out of your speculation about the problem and constitutes an answer to your Research Question? Use Workbook 6 sections 6.2, 6.3, 6.7.4 and 6.9. (You should be very careful not to confuse target and outcome in this work)

Apply a methodology to
the work place to get

SSM

Conclusion

- You don't need to be a statistics expert to use statistical techniques (you have not been introduced to the mathematical explanations of chi-square)
- But you do need to have an analytical mind if you are to synthesise solutions to strategic business problems
- So, basic statistics can be an SBIT consultant's best friend!

21

3 groups,

or any other element

Show me ~~that~~ that the education is not important

- This variable is sometimes referred to as the control variable because it may reveal how the relationship between the row and column variables changes when you "control" for the effects of the third variable.
- Any significance value below 0.05 is considered significant and not due to chance ('less than 5% chance that the two variables are not related')

13

- If you look at the table of chi-square statistics, you can easily see that in all but one of the education categories, the apparent relationship between income and PDA ownership disappears (typically, a significance value less than 0.05 is considered "significant").

14

- This suggests that the apparent relationship between income and PDA ownership is merely an artefact of the underlying relationship between education level and PDA ownership.
- In other words, the apparent relationship between income and PDA ownership disappears when another variable is used as a 'control' to check whether the relationship is real.

15

- Since income tends to rise as education rises, apparent relationships between income and other variables may actually be the result of differences in education.
- How can the hypothesis that it is the level of education that is strongly related to PDA ownership be tested?

16

So it's plain
that income
is related to
PDA ownership

من فوائد الشراء ← توجد المعلومات الخاصة بكل شخص
وتحليلها وتوجد العلاقات

العمل التي تؤثر على شراء الناس

First steps

- Assume you know nothing about the electronic consumer industry...
- So, you have no hypotheses initially
- But, you do have a grasp of some basic analytical techniques to use on the data
- So, let's look at the data...

- What factors affect the products that people buy? The most obvious is probably how much money people have to spend. In this example, we'll examine the [relationship] between income level and PDA (personal digital assistant) ownership.

(العلاقة بين الدخل ومستوى ملكية PDA)

Analysis types

→ SPSS Data Editor
110 pounds.
Demo

- None of the numbers in this table, however, stand out in any obvious way, indicating any obvious relationship between the variables.
- It is often difficult to analyze a cross-tabulation simply by looking at the simple counts in each cell.

- The fact that there are more than twice as many PDA owners in the \$25,000 - \$49,000 income category than in the under \$25,000 category may not mean much (or anything) since there are also more than twice as many people in that income category.
- We could try to ask for percentages instead of raw counts.

① # Crosstabs

② # Correlations (direction of relation).

what to do (it is only like background/introduction)

6. The project aims to identify key issues in this field, define areas of current and future research into the field, and prescribe solutions to dilemmas and issues arising, suggesting key areas of research and design, and suggestions as to the future. It will aim to call upon the experiences of those in the workplace, those who develop such interfaces, and the contact of those in academic research into the area, as well as existing studies.
7. Organization face to strongest rivals at economy ages that product life cycle is changed extremely fast and lacks a hypothesis into IT infrastructure as handle rapidly changing business model. Finally, organization is inefficient and lacks a knowledge creative a new product and loss a market place.
8. The problem theme is that the low accuracy of inventory records for existing inventory systems because of out-dated information. Example, querying those old PCs owned memory less than 32MB, the "old" system provided wrong information in such case.

focus the word problem.
Bad English.

confused about his own problem.

Exercise 2

Use the above construction process (CAPE) to define and refine your own research problem.

more than 3 sentences that means he
don't know what he is the problem.

It is an interesting exercise to ask a group of people what, for them, are the connotations of the word "problem". Bryant (1989) suggest the following list as typical:

Problem - a number of alternatives: something that needs solving, something that needs to be changed, something that causes frustration, disagreement over action, a fault has occurred, a barrier to progress etc.

The Mayer definition, simply expressed, means we have some known facts and a desired outcome - in this sense problem solving may be considered as finding an algorithm or transformation (a design) that moves us from one state to the other. In practice, solving real-world problems may be difficult because:

Formulation - the problem definition may be difficult to formulate

Equivalence - The problem definition may be expressible in many equivalent ways

Solutions - A given problem may have one, many or no solutions.

Even if a solution can be found it may be unsatisfactory

We usually have no way of showing that it is correct or even optimal

Sometime we accept a solution because it works, not because we know it to be correct or optimal

Common Faults in Problem Definitions:

Here are the most common faults we see when we look at problem definitions

- Listing many problems,
- Stating the problem as something to do,
- Stating the problem as being something is missing
- Stating a solution not a problem,
- Stating the problem is the problem
- Trivial problems,
- Non strategic business IT problems,
- Not stating a problem at all.

In this list there are three main areas of concern and they are representative of very shallow thinking and I describe them more fully here.

The problem is what I have to do

A large number of students are stating the problem in terms of what they are going to do. This will ALWAYS mean rejection because they do not even know what a problem definition is let alone being to define their own. That is they write something like "my problems is that I have to collect data and draw a conclusion"

The Problem is the Problem

What far too many students write amounts to: my problem is to find an answer to the problem – this of course is obvious but takes us nowhere. Problems are objects not an activities.

For example, stating the problem as "how to ride a bicycle" is incorrect since this is not the problem it's a question about the problem - the problem is "balance when riding a bicycle" and once I know this I can think about defining it in more detail. When you are clear about the problem you can then think about solutions so in this case I might think of several solutions: a training plan, put stabilisers on the bike, use a tandem as practice and so on. In other words a clear problem definition gives you liberty to think about a whole range of possible solutions.

Similarly I see lines like: "My problem is to find the best way to implement Wi-Fi security" - now this is definitely of the form "my problem is to find a way to solve the problem". Clearly here the problem is about "Wi-Fi security" but it's hopeless to think that just saying those words amounts to a definition and what we will be looking for is for it to be defined in some sensible way. Only then can you start looking for ways in which it might be solved. Almost always when we see the above form the student already has a particular solution in mind so the whole outline is just a pretence at going through the motions of setting up a research project but without any notion of what problem is at the heart of this work.

Policy Model

A policy is an expression of a prudent mechanism for controlling or limiting actions based on an underlying ethic as expressed in the Company/Organisation mission. So for example, in the University we have a policy for assessment and that controls and limits what departments may do. A policy is most often accompanied by a strategy to deal with various aspect of the policy. A good way to think about a policy is to see it as having four elements:

P - Principles that are based on organisational values or on legislative or contractual elements

L - Links to other organisational policies or other documentary sources. If you are not careful here you will find yourself overwriting or changing other policies that already exist in your organisation instead of referring to them.

O - Definitions of the objects to be controlled

T - Track or monitoring elements that set limits on what is permissible. This element will form the bulk of the policy definitions

Therefore the construction process is to set out the principles involved and make sure you are aware of any other related or relevant policies, legislative element or contractual elements. Once the groundwork is done you can set about defining the object to be controlled and lastly set up how they are to be tracked and monitored.

Guidelines

These are just advice notes. These are used instead of policies where it is not possible or desirable to absolutely control some activity or activities but we want to encourage some limitations.

Deliberative

The functional means by which values, issues, strengths and aims are debated to formulate a policy or strategy

Executive

The person responsible for ensuring that actions are taken and their outcomes monitored

Strategic Plans

Strategic plans are action specified at a high (relatively) level of resolution – that is they say what actions are needed and not necessarily how those actions are achieved in practice. It is helpful to think how a strategic plan is constructed as based on one or more of the following items although implicitly all of them are always involved.

V - Build your plan on a set of values that you set your organisation

I - Build your plan by looking at issues (needs if you like)

S - Build your plan by looking at your strengths – concentrate on what you do well

A - Build your plan based on aims that you have set

The process whereby one develops a strategy is very simple. All one does is take lets say an issue (problem) and by a process of deduction arrive at an activity or perhaps a set of activities that acting together will remove the problem. To be practical on needs to not just state the action but describe it and monitor it. The strategic plan then just essentially lists the actions needed and how they will be monitored in some sensible structured manner. Often organisations have set guidelines on how plans are to be set out and when that exists one must follow them.

Ethical Viewpoint

The basis of the ethical viewpoint is that the University is always seeking to achieve the highest standards in every respect related to its mission and to enhance and maintain that position. Briefly:

The requirement is for excellence with a distinct character related to a given organisation.

The standards relating to contractual, academic, financial and ethical considerations must be applied impartially everywhere and be of such a probity that they can be defended anywhere.

Actions

Actions are implicit in many of the things we write about. However, they are always expressed to a certain degree of resolution. This implies that an action in a strategic plan at University level of resolution translates into several actions at departmental level of resolution.

Action Plans

These are detailed plans for implementing a strategy

Best Practice

Many processes and procedures will be present in the system and all we do is identify and define them unambiguously. It follows that to develop best practice one has to define what practices are available. Now in all likelihood there will be several ways of doing almost anything and so if one wants to progress it is necessary to identify the best of these practices and use that as the standard until something better comes along. In simple terms: identify practices; decide which ones are good practices and eventually which one might be classified as best practice. Best practice is likely to be a matter of expert professional judgment but can be identified by the following elements:

- Generates a well-defined outcome (not outcomes).
- Is often recognised as plain common sense.
- Fits in well with existing procedures and processes.
- Cost effective.
- Efficient.
- Can be learned and in that sense described in a document

Code of Practice

These are guidance notes that set out what has been generally recognised as best practice for a whole industry.

What are Quality Standards

There are several ways it is possible to define procedures depending on our particular view of what is meant by quality. However, a good working definition is as follows:

Quality standards define, at an appropriate level of resolution, the procedure or procedures necessary to guarantee a desired outcome.

Standards are not to be seen as a lowest common denominator upon which everyone can agree. Standards produced in this way are almost always unhelpful.

Standards are not fixed for all time and one would expect that they would evolve as more and more domain specific knowledge is gained.

Standards are not primarily a mechanism for punishing those who fail to achieve quality improvements

Exercise 001b.01.a – Target and Outcome

Target – the real-world effect that you want to produce. Usually targets are introduced by a verb: improved network infrastructure, strategic Technology alignment, reduce network down time, a heightened awareness of security etc.

Outcome – this is what you produce as part of your project, dissertation or thesis. As we have seen the idea is that we can use this outcome to generate the target effects. Outcomes are objects and so tend to be stated as nouns: a model, an explanation of some behavior, a usage protocol, a feasibility report, a post implementation review etc

Features of an outcome – it can be written down, it easily observable, it can be placed in a document, it can be sent to Portsmouth for marking. If it is any or all of these it's probably an outcome.

Exercise 1

In the following table look at the named object and the try to decide whether it is likely to be regarded as a target (T) or and outcome (O) for your MSc project and then add a little note of explanation.

is it effect? (The effect) Target / outcome [Hard Copy]

	Project Object	T	O	Rationale
1	A strategy		X	It can be written down and sent to Portsmouth
2	Increased productivity	X		Not easily observable but is clearly an effect
3	Better fit with technology	X		Not easily observable but is clearly an effects
4	A best Practice Model		X	It can be constructed and documented and sent to Portsmouth
5	Improved sales	X		An effect but it cannot be sent to Portsmouth for marking
6	A security policy		X	It can be written down and sent to Portsmouth
7	Highly usable systems	X		Not easily observable and cannot be sent to Portsmouth
8	Efficient network control	X		Not easily observable and cannot be sent to Portsmouth
9	A pattern of work		X	It can be described and sent to Portsmouth
10	A process flow		X	It can be described and sent to Portsmouth
11	Simpler Web Page Access	X		An effect but cannot really be sent to Portsmouth
12	A role description		X	It can be written down and sent to Portsmouth
13	Better trained operators	X		Not easily observable and cannot be sent to Portsmouth
14	A list of functions		X	They can be written down and sent to Portsmouth
15	A theory		X	It can be written down and sent to Portsmouth
16	A feasibility report		X	It can be written down and sent to Portsmouth
17	A computerised sales program		X	It can be constructed and see in action and sent to Portsmouth
18	Improved Management Competence	X		Observable effect but it cannot be sent to Portsmouth
19	A predicative report		X	It can be written down and sent to Portsmouth
20	A process description		X	It can be written down and sent to Portsmouth
21	A model or framework description		X	It can be written down and sent to Portsmouth
22	Improved IT management	X		Not easily observable and cannot be sent to Portsmouth
23	A definition or set of definitions		X	They can be written down and sent to Portsmouth
24	A comparison matrix		X	It can be constructed and sent to Portsmouth
25	A design catalogue		X	It can be written down and sent to Portsmouth
26	Reduced number of security violations	X		Not easily observable and cannot be sent to Portsmouth
27	A security protocol		X	It can be written down and sent to Portsmouth
28	More secure passwords	X		Not easily observable and cannot be sent to Portsmouth
29	System Requirements		x	These can obviously be written down
29	Elevated Business Focus	X		Sound like a good business idea but cannot be sent to Portsmouth

Exercise 2

For the ones you marked as probable targets in exercise one, write down a possible MSc project outcome forms that might reasonably be thought of as generating or going some way to generating that intended target. (Do not assume that because there are 15 spaces there are that many targets in the above)

My answers are just suggestions as to choices of something that could reasonably be expected to get us to the target. It is very unlikely that you have the same ideas but be guided by what I have written as to the suitability of your own answer.

	Project Target Name	Possible outcomes for those that are targets
1	Increased productivity	A report outlining a new training model
2	Better fit with technology	A report which reviews current technology and its impact on productivity
3	Improved sales	A strategy document on better use of email
4	Highly usable systems	An feasibility report looking at a new IT interface arrangement
5	Efficient network control	A portfolio of network best practice management scenarios
6	Simpler Web Page Access	A set of program outlines
7	Better trained operators	A training plan
8	Improved Management Competence	A framework (model if you like) of required competences
9	Improved IT management	A required skills assessment
10	Reduced number of security violations	A computer usage policy
11	More secure passwords	A procedure for testing passwords for strength
12	Elevated Business Focus	A recommendation to implement say outsourcing

Ideas 003a.01 – Qualitative Data Processing Mechanisms

Many projects in technology deal with qualitative data and this note just outlines the sort of things you can do at the pre-processing stage in your research design.

Introduction

It is very important to keep notes of interviews, observations or notes as you read through documents and make sure they are structured and accurate otherwise you will find your biases coming out in the results – that is you will interpret what you find the way you would like them to be.

As you know there are two phases of processing in research. The first one is all about assembling your primary data collection and the second phase is to process the collection into the intended outcome. Don't fall into the trap, as many students do, of collecting that data and then ignoring it as far as getting an outcome is concerned and that can only have one result – fail.

PLEASE remember the processing activities suggested here are not designed to generate a project outcome - these are really pre-processing stages to analyse the data ready for you to construct your project outcome. So be WARNED - if all you do for example is apply several of these activities to your data then normally that will NOT be regarded as generating your project outcome.

So for example suppose I have a set of interview transcripts and a set of observation notes all collected in an attempt let's say to generate as my project outcome - a best practice portfolio on internal software application development. So I might for example process this data (transcripts and observation notes) to get: common threads, outliers and labelling but obviously those three lists cannot possibly be regarded as my best practice portfolio but they are a necessary step toward me generating it.

Processing Ideas

These are the most common ideas that one typically uses to look at qualitative data. I am not suggesting you use all of them but usually as the data emerges from your collection process you will start to get a feel for which ones might be the most useful.

Commonly, people use a spreadsheet, Word or Database to deal with all this although it can also be done by hand. My preferences would always be a database because of the potential for indexing, searching or linking it to other data sets or even links within itself.

Common Threads - Are there common response threads running through your interviews, observations or documents as these indicate a shared understanding in your sample and might be useful in formulating the project outcome.

Usual process - use a tabular method to collect this evidence together by listing the themes and counting occurrences and variations.

Outliers - It is often useful to look for extreme or unusual opinion or events and they might point to serious problems in the situation you are investigating. These indicate that the understanding is not shared and often mean that further investigation and may lead to very useful insights.

Usual process – use the same tabular record used for common threads but look for item on it where the opinion is in different, unusual or extreme with very little agreement with any other sources with virtually no commonality.

Word Frequency - You can construct a concordance and look at how frequently words are used and of course it also gives you the situation vocabulary.

Usual Process – use a software tool to generate the list of all words used and their frequencies. In fact it may be quite interesting to see how wide the vocabulary is as this might give you another “handle” on the problem theme. I would not recommend you try to do this manually unless the transcript or documents are of a very limited nature. Unfortunately, if the documents are not in an electronic form (unusual these days) then a manual process is the only one possible.

Meaning - Make sure you know the meaning of any words used and what kinds of words are used: descriptive, explanatory, critical and so on

Usual Process – using a constructed concordance or glossary to list out all the words used and then for the important ones or ones where you do not understand the meaning write a definition.

Semantics – this is just an extension of “meaning” but here you are trying to ensure that you understand what has been said – so one might look at phrases or sentences for example. This needs a lot of care because it is all too easy to see a meaning that you would like to see and not the one that is actually part of the data. It is unfortunately all too common for students to write what they think is a simplification in their own words or substitute an accepted situation word or words for one of their own and this can often turn out to be disastrous.

Usual Process – it is hard to find an absolutely secure process here because a certain amount of domain expertise is always needed. However, a reasonable plan is to look for and write down the key ideas in the phrase or sentence because if you have the key idea then in practice one understands what is being said. One almost always does this in conjunction with the tabulated themes because themes themselves might be an object, an activity or an idea.

Labelling - It is often interesting to look at how situation elements are labelled. For example, the software might be labelled as ‘useless’ or ‘difficult’ by users or the managers labelled as ‘arrogant’, ‘unhelpful’ or ‘lazy’. When this happens it may indicate serious problems in the situation.

Usual Process – using a constructed concordance or glossary to list out all the words used and then for what you regard as a label search for them in the list.

Structures - You can partition the answers into such things as: opinions, definition, explanation, theories, concepts, methods, policies, governance, training, environment, attitudes and so on or any other categorisation that you can identify. This will help to ensure that you have a good understanding of the situation as seen from interviews or documents.

Usual Process – use your tabulated list of themes and then add extra columns to code the structure that you have identified or want to use. Remember that an element may have more than one structure – something could be a definition but also be expressed in the form of an opinion.

Response Validity - Always ask is the response valid or relevant in that situation or can it be discarded. The reason you want to do it is because you don’t want to be encumbered by data that has no value and one is always looking to get the smallest valid data set.

Usual Process – this is not easy to do and it requires good to very good domain knowledge. I would recommend you try to generate a few simple questions that you apply to the data and if they all give a yes answer then accept the data. This might be things like: “is it a common opinion”, “is it a fact”, “is it interesting or insightful” that sort of thing but don’t have too many questions else you will end up with no valid data!

Response Reliability - Always ask how reliable is the data that you find or are given - this is to do with how the interview or search was carried out and can you rely on it as being truthful.

Usual Process - Essentially we ask would we get the same result if we did the interview/search again.

Significance - Can you identify items that are clearly significant in this situation – significance here means that the response is representative of something genuine.

Usual Process – just look at the tabulated frequencies for the main themes, labels and significant words used. One cannot be certain from just frequency that it is significant so one must also weight it up in your mind against your research question and whether you can do something with the data. For example, to be flippant one might get a common theme emerging that there is not enough car park space and things like that it is almost certain you can do nothing about.

Generalise - Is there anything that leads you to make generalisations.

Usual Process – essentially what one does is look at themes, labels, outliers and knowing these have emerged from a sample we now try say what it might mean for the whole company - can it apply to the whole company, is there some important element in this theme that has a much wider implications, is there a principles that can be established, can I construct a theory and so on.

Try to remember that you may need to do all the above for each different group that you interview or documents that you look at or situations that you observe, as there may be differences or links between the groups which you want to identify.

Read Saunders chapter 9 starting at page 245. Pay particular attention to quality issues on page 253 and the themes idea on page 255. Finally be sure you or anyone you employ is competent to carry out the interviews, document searches and so on - so read pages 262-264.

1 - Contextualisation and Selecting a Research Method

Problem - just remind yourself of the single problem theme that this research was trying to resolve

Target - just remind yourself of the principle target of this research and recall that targets are effects that we want to generate by using our outcome that when used will create effects that amount to a solution to the problem stated. Do not fall into the trap of naming an object instead of an effect or stating the location of the effect and not the effect itself. So it would be quite wrong to say my target is a "new software model" as that is an object and what we want here is the effects created in the real world of using that model. Similarly, don't say "my target is the help desk staff" because that points to a location not an effect on the help desk staff or what they might do.

Outcome - This MUST be the same as you stated in the relevant section and in the aim. Possible and common outcomes are expressed as: reports, position papers, models, frameworks, catalogues, best practice descriptions, process portfolios, policies, strategies, reviews, requirements documents, process descriptions, role profiles, factor or task illustrations, people or situation portraits, critiques and so on but its key characteristic is that it is typically a document of some kind and may be expressed as text or diagrams or a mixture of both.

Research Question - just recall to mind this element because it summarises what your whole project is about. It has 5 elements which may be stated as **SPITS** - Spotlight (data), Problem, Interrogative, Target and Suggestion though not necessarily written out in that order.

Research Method - Here one requires a rational choice of method based on a consideration of the data, the situation and the typical criteria applied to the method. Possibilities are: case studies, surveys, experiments, grounded theory, action research, requirements gathering, histories, vignettes, quasi-experiments, biographies, histories etc. Make sure you look at the criteria usually associated with each of these research models - don't assume you know and don't try as a rational justification a quotation from a book as these can only be generalisations.

2 - Defining and Collecting the Data

BAGeD - This is the KEY part of the thought process of defining the primary data; you try to put a sharp spotlight on just the primary data that you need - perhaps the best way is to think as clearly as you can when deciding on the activity that it points to what you must write down as data. Here are some common words to help you think about your basic activity: account for, analyse, appraise, assess, catalogue, collect, compare, contrast, criticise, define, describe, differentiate, discuss, evaluate, examine, explain, explore, illustrate, interpret, justify, link, outline, portray, profile, represent, summarise, synthesise and so on. Make sure you KNOW what these words means don't just arrogantly assume you know - this list is to help you think and it's not to be used to just pick anything that sounds as if it might be right.

Primary Data Items - This is where you try to say what exactly you are looking for as data items. This will normally require very careful thinking if you are to arrive at something sensible, identifiable, worthwhile and collectable.

Location - Here you must state where the data is located and sensibly and practically consider if you can get access to it. Try to be practical as far too often we see impossible plans for example wanting to interview 50 management directors or trying to use observation for getting data from an ATM.

Sample size - This will vary considerable depending on the research method you choose. In most case it is only totally applicable when there is a survey and there is a table in the set book on how to calculate a sample size. In all other case it's a matter of working out what you can do in the time available to you

Collection Protocol - The data has to be physically collected and here you must be precise as to how that can be done based on the data itself and on a consideration of it location. The most common mechanisms employed are: interview, questionnaire, observation, role playing, seminar, focus groups and document searching.

Selection protocol - You must know exactly who or where you will get data from. The exact description will depend on the Research Method chosen coupled with a consideration of the collection protocol. So if we were using a survey we need a precise definition to say how we pick our sample points and what data we collect from them.

Recording Method - All data has to be recorded so one needs to plan how that will be done. Possibilities are: note taking, reports/transcripts, form filling, audio recording, video recording, computer logging or searching, excerpts from documents and so on.

Presentation of Raw Primary Data - All you data has to be available for inspection and so you have to provide it to your project readers in some form. Most often it is in a tabular or catalogue summarised form and placed in the project appendix.

3 – Generating the Intended outcome from the Structured Collection of Primary Data

Pre-processing - The primary data as collected is not always suitable for use in the final phase of generating the project outcome so at this stage one must pre-process it to get a structured collection of some kind. For example, if ones raw primary data was in the form of interview summarised transcripts then one would go through each transcript categorising that data found there into say a table of some kind using normal text processing ideas. Similarly, if one has a series of vignettes one would create a concise and lucid illustration from each one. If it was a set of questionnaires one might decide to structure it into a series of charts and from those charts one could generate the project outcome.

You have to try to say how this processing is done. It will NOT be sufficient to say something like "I will look through the data and form a catalogue" or something equally vague. Try to be as precise as you can without being excruciatingly pedantic. Commonly students think of things such as categorising the data into subgroups or factors, simply setting a priority on items in a list in some way, using a well defined procedure to transform the items, using some form of matching or linking process or using a model or framework of some kind to transform the basic data into something more useful.

It is also quite common to use secondary data or the literature to help with this stage, for example there might be a company wide procedure for say prioritising tasks or there might be a standard list of variables that can be used to match common factors in interview transcripts.

Form of structured Primary Data Collection – this section goes with the pre-processing and it simply means you try to decide by looking at your outcome what would be the best form in which to present your structured collection of primary data. The most common forms are: a series of charts or tables, a catalogue of some kind, a set of illustrations, a list and description, a prioritised list and description, a matrix arrangement of some kind with statistics, a matching list and so on.

Outcome processing – this is the last stage of processing and here one takes the structured collection and from it generates the intended outcome. Again you must define HOW this will be done. It will in no way be sufficient to say things like "I will examine the data and draw conclusions" or "after careful analysis of the data I will generate my policy" – if you do that your work will register as a fail because by saying making such vague statements you are telling the world that you have no idea what to do with the data and only just managing to tell the world that you know something has to be done with it.

The methods you use here may be quite similar to what you do in pre-processing but typically at this stage one tends to rely on models of some kind. You should note that in pre-processing we are largely just re-presenting the same data in a more useful form. But in outcome processing we are typically trying to generate a single object of some kind such as those listed in section 1 above but I copy them here for convenience: reports, position papers, models, frameworks, catalogues, best practice descriptions, policies, strategies, reviews, requirements documents, process descriptions, role profiles, factor or task illustrations, people or situation portraits, critiques and so on but its key characteristic is that it is typically a document of some kind and may be text or diagrams or a mixture of both.

Example Part 1 – Contextualisation and Selecting a Research Method (extracted from student work)

Problem – Post Merger Integration is crucial success element in any given merger because it enables common business processes and economies of scale. IT underpins most critical business processes and the system integration process and infrastructures will accelerate or delay the overall business merger.

Target - A reduction in the timescale needed to integrate IT in a post-merger environment, allowing a company to achieve cost and efficiency benefits soonest.

Outcome - A documented standard model for the planning and implementation of a merger based IT integration process.

Research Question – How (interrogative) can IT performance of disparate systems (problem) be enhanced to accelerate the process of post merger integration (target) by examining the system integration process (spotlight) in order to define an IT integration model for planning and implementation. (Suggestion).

Please be aware that it is not necessary or particularly describable that in your final work you add in the SPITS words – they are here for illustrative purposes only but if it helps you at the early stage that is fine

Research Method - The data that is the basis for this research has recently become accessible as well as the individuals who were involved in the PMI (post merger integration) of IT. To fully understand the actions and activities in post-merger IT integration events one must appreciate both the immediate context and longer term implication. This can be done by critically reflecting on situations that have occurred as a kind of model leading to greater insight into the problem area. It therefore seems worthwhile in this case to use the Biographies/Histories research method to best trace the progress of some sample completed merger integrations and by a process of evaluation and understanding of the decisions taken and activities that occurred, as well as to solicit feedback.

Example Part 2 – Defining and Collecting the Data

BAGeD - The key activity here is to identify and explore IT integration activities performed and decisions made by individuals and groups in a pre-merger situation and post-merger reviews.

Primary Data Items – The significant activity/decision data made at the pre-merger stage needed to generate the stated outcome would fall within broad areas (in the context of PMI) such as: pre-merger assessments and information gathering, planning, implementation and reviewing and would include instances of decisions and resource allocation affecting project flow.

The significant activities/decisions data made at the post merger IT integration with consist of an impact assessment using the broad areas of pre-merger assessment, information gathering, planning, implementation and review. There will be a specific focus on the use of: planning tools, data collection protocols, allocation of resources, deliverables, decision making constraints, in house skills, etc).

Location - The primary source of the historical data would be employees of ABC Media and any documents produced as part of the IT integration process. Employees that were involved in planning, directing or deemed as having significant influence on the process will initially be identified via the Technology Director leading the IT integration and the Operations Director, who were leading the business integration and then via contact with the individuals identified and any additional locations as recommended by them.

Sample size – not applicable in this case

Collection Protocol - To fully explore the decision making process and explain actions there will need to be interactive elements to primary data collection. Therefore a mixture of semi-structured and in-depth interviews coupled with document analysis.

Selection protocol - The criteria for the sample of interviews will be Directors, IT Dept managers and defined Technical Leads who were directly involved in the IT integration and a selection of Business managers because their system requirements were obviously influential.

Recording Method – Written notes/transcripts will be taken during the interview and where possible audio recordings will be used. These will all be support by document extracts.

Presentation of Raw Primary Data – The primary data will essentially be presented as interview transcripts, selected integration documents and illustrations of the various activities/decisions and will be available in the appendix of the project.

Example Part 3 – Generating the Intended outcome from the Structured Collection of Primary Data

Pre-processing – In order to structure the data the transcripts, documents extracts and illustrations will be processed to establish a base cluster of activities, pivotal events, dependencies, interactions and the performance and criticality of these items. These groups will largely be identified by the managers involved in the work but additionally the will be a layer of analysis that searches for:

Identification of common themes in situations, activities, decisions or influences.

Comments or descriptions of events that could be viewed as unusual, extreme or attaching positive or negative labels.

Frequency of words used (focusing on planning or activity based e.g. "Requirements" or "Testing", but not limited to these), indicating either the commonality of an issue or its significance.

Form of structured Primary Data Collection – the structured primary data will be presented as a process/decision catalogue which might also include charts and diagrams.

Outcome processing – Here I am looking to eventually produce a model for the IT planning and integration process so I will use the usual model idea of linking activities and processes. Using the catalogue produced in the pre-processing stage and thinking of the interaction practice as a flow of events it may be beneficial to treat it as a form of system driving towards the goal of integration.

Given this, the data may best be interpreted with the aid of tools from Soft Systems Methodology starting with a Rich Pictures to aid with understanding, interpretation and the sharing of perceptions on of specific events. From this we may use the basic SSM tools of Relevant Systems and Root Definitions and hence move to the conceptual modelling stage and thus after processing through an SSM agenda a proposed model for the technology integration process will be developed and presented.

Exercise 004b.01a – Finding a Basic Activity Word Spotlight

Exercise 1 - Write some notes to explain to fellow students what the following verbs might mean in practice.

Account for	Explain and clarify something by giving reasons
Analyse	Resolve something into its component part, or examine critically and minutely.
Appraise	This is best thought of as something like forming an opinion about something. It might be quite simple such as forming an opinion as to whether something is good or bad but more often that not it's about forming an opinion about something after assessment or evaluation with regard to what can be done - so we might appraise whether a process for example should be left unchanged, modified or made redundant
Assess	Determine the value of something. Similar to evaluation but it is often useful to think of evaluation as a qualitative process and assessment as a quantitative one.
Catalogue	This means to create an order collection of some sort where there is a logical order and the essence of the task is to enumerate and describe
Collect	This is very simple as all one does is to identify the data and literally collect it as you see it. So if I were looking for SPAM instances then as soon as I find one I just file the whole SPAM email away for later processing.
Compare	Look for similarities between one or more things.
Contrast	Look for differences between one or more things.
Criticise	Make a judgement, backed by a discussion of the evidence or reasoning involved, about the merits of theories, opinions, plans and so on.
Define	State the exact meaning you are attaching to a word, phrase, idea, process etc
Describe	This may be used freely to describe in detail situations, events, opinions, feelings and so on.
Differentiate	Look for differences between things
Discuss	Explain something by given two sides of the argument
Evaluate	In some cases one might want to look at events or people or processes in order to form an evaluation and that collection of (usually) small evaluations form our primary data.
Examine	Look carefully at the details of an argument, theory, or plan etc
Explain	Explain - this is about saying why something is. So one can describe an event but also explain why it occurred

Explore	You can use this word but we are always exploring so it must be used with care. Typically, in these case one starts with a model of some kind and uses that to inform the exploration process. For example, we might have a theoretical process map and we use it to explore various working processes to see if we can find flaws or weaknesses and then those descriptions of flaws or weaknesses become out primary data.
Illustrate	Here one is trying to find a way to expresses in a very pointed way some situation or thing. So one might identify an instance of SPAM and then illustrate why it might be harmful and so that adds poignancy to the example you have extracted. Mostly, it is best to think of illustration as a way of giving an example but in that example you want to make just one clear point.
Interpret	The essence here is that one is typically observing something to describe it but also to find some meaning in what is being done. This is often used when looking at social groups or situations where it is not always obvious why certain actions occur
Justify	Show adequate grounds for decisions and conclusions and answer the main objections likely to be made about them.
Link	This is often a neat way of dealing with some types of data where you think there is a relation but the relation itself is not known with any certainty. On often find this kind of activity evidences in a matrix formulation or representation.
Outline	Give the main feature or principles of a object, omitting minor details and emphasising structure and arrangement
Portray	This might be a useful verb if you were looking for types in a study. For example, if you were looking for people who get involved in illegal downloads one might want to portray them in some way.
Profile	This is similar to a description but it focuses on just the key points. For example, if we were looking for best practice in a situation then we might start by just profiling a given task – that is we outline the main steps and rational to start with. The idea is similar to an outline but implies deliberate section of certain aspects.
Represent	Sometimes you might plan to build a representation of some event as you primary data. For instance, if one was looking for security awareness in employees then of course one cannot "see" it or collect it as such. In these cases we must try to find a way of representing an awareness level or feeling and that representation forms our data.
Summarise	Give a concise and lucid explanation or account of something, presenting the chief factors and omitting minor details and examples
Synthesise	Resolve something into a whole from its component part.

Exercise 2

Suppose that my BAGeD was to LINK (my basic activity) a security violation with a particular user behaviour - that will generate a primary data item (implicit here is that we also need a description of each violation and user behaviour). Use this basis idea and write a complete data collection phase from it.

Data Collection Process

In this case I am combining my BAGeD with a pre-processing stage to get my useful primary data collection.

When complete I will have a collection (perhaps 1000s) of pairs of values (violation and user behaviours) and now I must process the whole collection to get my intended project outcome.

Let us suppose that my intended outcome is to producer a company wide policy on framework for use by IT implementations. To do this I must have a process so I start by forming a matrix of violation linked to a user behaviour and in a second pre-processing stage I prioritise the list by violation severity. Here you must realise that I have to know how to describe the severity of a violation, I cannot just make it up. Let us suppose I do it by looking at extent – that is I ask what is the extent of the violation: local to the PC, local to a particular system, local to the intranet or global to the company.

In my last step I need no to use the prioritised matrix to develop a security policy. Therefore I might search for an appropriate BS to guide me in the process or I might use a method called PLOT – but whatever I use it has to be such that it can be repeated by another person. The whole purpose of the process is that I can then draw up a policy that might eliminate these inappropriate user behaviours.

MSc Degree Structure

Research Methods – 12 weeks or 150 hours study for 15 credits

Research Ideas and principles

Statistics

Project – at least 18 weeks or 450 hours for 45 credits (about 15,000 words)

A research project of your own choice but University Approved

Project must have a strategic business IT outcome

Project must involve significant IT learning

1

Work Schedule – Research Methods

Research Methods Steps (parts of the assessment package)

Assessment 1a Part 1 – get approval for a project idea

Assessment 1a Part 2 – online tests

Assessment 1a Part 3 – Literature Review & Project Specification

Assessment 2 – Statistics

Supervisor appointed and Research Project starts

2

Student Progress Marks and Warnings

During Research Method unit progress marks are awarded

One attempt at each of 5 online test to gain a maximum of 5 marks

One attempt to gain project approval for a maximum of 10 marks

Deadlines – failure to meet due dates will normally mean unit failure

Assessment Instructions – failure to follow instructions means failure

English – if your language is judged poor then project cannot start

3

Project Styles

Engineering - where you build something such as a web site, invoicing system, requirements document etc

Study - where you look at a problem related to a topic area such as might occur in the use of say IT collaboration Tools

Review - where you review a topic of current interest by looking only at primary sources: journals or reports. This style will ONLY be allowed in exceptional cases where the topic is based on a new technical idea and the student can get access to journals and reports.

4

Degree and Project Style

Engineering Style Project

MSc Internet Systems Design

MSc eCommerce and Marketing

Study and Review Style Projects

MSc eCommerce and Marketing

MSc Marketing and eCommerce

MSc Strategic Business IT

5

Summary of what we will do

Define – Problem and associated target

Research Question – at a minimum linking problem and target

Outcome – the object to be generated: model, report, theory, a matrix,...

Aim – to link outcome and target

Objectives – a set of activities that generate minor project outcomes

Research Design Part 1 – define the data and state how it is to be collected

Research Design Part 2 – process the collected primary data to get the outcome

6

Basic Research Structure

Topic Area – this just define the general area in which you are working This is a simple step and although part of the process is not a key elements in focusing

Problem – define a single significant problem

Target – say what real-world effects will be produced if we can solve the problem

Research Question – a lucid question that links problem, target, outcome and data

Outcome – what is it that you can produce that will generate the target effects

7

Cyclic Research Structure

```

graph TD
    Problem --> Target
    Target --> Speculation
    Speculation --> Outcome
    Outcome --> Problem
  
```

8

Key Research Process

Suppose your problem is lack of sales staff productivity

Then my target might be higher sales revenue

So I speculate that this low productivity might be due to lack of training, poor customer records, poor IT infrastructure, inefficient email, etc. But I decide email is a major cause of this problem

Next I collect data on email usage practices amongst sales staff

I process the data to produce my project outcome – a report that defines a set of Best Practice Strategies for email management

I generate this Best Practice Strategy outcome because I believe it will help resolve the email problem and hence I get to my target.

9

An Important Distinction

Problem - is something that is a matter of concern or debate in a given situation

Target – this is the real-world effect that you want to produce. It might be things like: improved network infrastructure, strategic Technology alignment, reduce network down time, a heightened awareness of security etc. (VERBS)

Outcome – this is what you produce as part of your project, dissertation or thesis. As we have seen the idea is that we can use this outcome to generate the target effects. Possible outcomes are: a model, an explanation of some behavior, a usage protocol, a feasibility report, a post implementation review etc (Nouns)

Features of an outcome - when you name your outcome ask: can I write it down, is it easily observable, can it be placed in a document, can it be sent to Portsmouth for marking. If it is any or all of these its probably an outcome

10

Can you make the Distinction

1. A strategy	15. A theory
2. Increased productivity	16. A feasibility report
3. Better fit with technology	17. A computerised sales program
4. A best Practice Model	18. A post implementation review
5. Improved sales	19. A predicative report
6. A security policy	20. A process description
7. Highly usable systems	21. A model or framework description
8. Efficient network control	22. Improve IT management
9. A pattern of work	23. A definition or set of definitions
10. A process flow	24. A comparison matrix
11. Simpler Web Page Access	25. A design
12. A role description	26. A methodology
13. Better trained operators	27. A security protocol
14. A list	28. Secure passwords

11

Projects must be Research Based

Research Based means you attempt to resolve a problem

Research Based means there will be a real-world effect if the problem can be solved and this effect is known as the target

Research Based means you have an idea as to what form a solution to the problem may take

Research Based means you define and collect original (primary) data that can be used to generate a form of solution to the problem

12

Primary Data

Primary Data - data that will not EXIST as a collection until YOU define and collect it for some purpose.

Primary Sources – the first recorded case of existing information contained in journals, reports, theses and some books.

Engineering Style: Primary data as the discovered requirements

Study Style: Primary data is as you define it and collect it, in for example in survey, document search, interview and so on

Review Style: Primary sources only

13

Primary Data Examples

Example 1. If I extract instances of phishing (problem) from an email log (secondary data) would that list of phishing instances be primary data?

Answer 1. It would be primary data even though the email log (secondary data) obviously exists, the list of phishing instances (my primary data collection) did not.

Example 2. If I conduct interviews in order to discover a user purpose regarding illegal downloads (problem) would my transcripts be primary data?

Answer 2. It would be primary data since interview transcripts did not exist before the interviews took place.

Example 3. If I read reports (secondary data) on security violations (problem) for a company with a view to identifying the root cause of each violation

Answer 3. even though the violation reports exist (secondary data) the list of root causes (my primary data) did not.

14

Research Question

This is a way of capturing problem, target, data and a suggested outcome into one lucid and concise question that will form the focus of your research

Structure – it has typically 5 elements that you might use but do not worry too much about the order in which you present them although it would be odd not to have the interrogative at the beginning. (SPITS for short)

-  **Spotlight** – what sort area will the data come from?
-  **Problem** – this is about focusing on the problem itself
-  **Interrogative** – what is question key (how, why, what etc)
-  **Target** – what sort of real world effect is being sought
-  **Suggestion** – what sort of outcome are we looking for

15

RQ Answer Forms

Interrogative words - Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, is/are, and can.

Question that use: does, is, are, what, when or can will expect as an answer a fixed list of possibilities: yes/no or low, medium, high, etc

Question that use: how, why, who or where will expect as an answer an explanation in the form of a: report, model, equation, theory, design, evaluation etc

Question that use: how, who or what will expect as an answer an exploration in the form of a: list, explanation, comparison matrix, pattern, survey report, a theory etc

Question that use: how, who or why will expect as an answer a description in the form of a: report, process or procedure, model, policy, strategy, theory etc

16

Research Question Example

How (interrogative) can the billing cycle (problem) be improved by identifying and defining a best practice portfolio (suggested outcome) in order to improve the quality of response (target) to customers by reviewing the initial accounting processes stages (data spotlight)?"

17

Common RQ Errors

Error Type 1: Not a Question - to an English speaker the following would not sound like a question, it would sound like a heading to a list of instructions or a procedure.

How to make business applications development productive at XYZ Corporation?

Error Type 2: Multiple Questions – It is not a good idea to try to put TWO (or more) questions into one as follows – (testing and bugs).

How can software bugs be minimised and the testing shortened in the development process of an Inventory Management system.

18

Common RQ Errors

Error Type 3 - Obvious Answer – these are cases when no research is needed because the answer is either obvious or common knowledge. Questions like this show a serious lack of thought – take the second example, it is easy to see that the answer is bound to be YES - of course a better work-life balance "CAN" (but might not) be obtained so there is nothing of any value whatsoever in a question like this.

How can a business application development process increase the productivity at XYZ?" or

Can a better work-life balance be achieved with telecommuting for technical personnel?"

19

Common RQ Errors

Error Type 4: The question is a solution – in this class of error the question is worded in such a way that it is in fact a solution. The trouble with doing this is that it cuts off any further speculation about dealing with this problem idea and so the question becomes rather pointless.

What strategic business indicators are available to drive the process of building a secure network infrastructure in order to ensure continuous business operations.

Here it looks as if the problem is "building secure network infrastructure" and what we want as a target is "continuous business operations". But in effect we are told to look for "strategic indicators" as a solution to this problem theme.

20

Project Research

Phase 1 – define and collect primary data

If I extract instances of phishing (problem) from an email log that would be primary data because even though the email log is secondary data, the list of phishing instances (my primary data collection) as a collection does not.

Phase 2 – process primary data collection to get an outcome

My purpose being to process this primary data collection to find out the most common sources of phishing and express my findings in an evaluatory report which outlines a management strategy (my form of answer).

21

Example – Study Project Set Up

Problem Theme: illegal downloads using up resources and increasing security risk

Target: improved worker productivity, efficient use of bandwidth and reduced infection risk

Speculation – here I might say the causes are to do with poor training, poor security, user ignorance of the dangers, no policy etc. But I settle on the lack of a policy.

Research Question: How can (interrogative) illegal download (problem) be prevented or reduced in order to improved worker productivity, gain an efficient use of bandwidth and a reduced infection risk (target) by an analysis of computer user Behaviors (data spotlight) by generating a security policy (suggestion).

With "How" we might expect an explanation answer and in this case it is expressed as a policy document because that limits and controls download behaviours.

Project Outcome: a security policy aimed at this activity because I think that it will generate the targets stated above.

22

The Research Process – an Analogy

Phase 1 is like working with a shopping list to collect a bag of ingredients (collection of the primary data) and phase 2 is like using a recipe for Combining them to make a cake (your intended outcome).

To reverse the analogy, if you were going to make a cake you would not just walk into a shop, just pick up a random set of ingredients and then mix them all together into some muddle and expect a cake to emerge - no one but an idiot would do that would they?

23

Research Methods

In research, usually we try to do one or more of the following: understand something, explore something, describe something, explain something, improve something, build something or prove something.

A Research Method is a model a framework in which you set your research design – this useful because each model will have features that suit what it is you are doing

Common Research Methods	Common Research Methods
Case Studies Vignettes Action Research Experiments Quasi-Experiments	Surveys Biographies/History Grounded Theory Ethnography Requirements Gathering

Research Methods Selection

Choosing a method will depend on many factors such as: context, time available, skill available, practicalities, access, reason for the study, what kind of outcome you want, cost, quantitative/qualitative, scale, control, sensitivity of the data and so on.

The simplest guide is to think about your basic intention – ask am I setting out to: understand, explore, describe, explain, improve, build or prove.

Common Research Methods

Case Studies	- understand
Vignettes	- explain
Action Research	- improve
Experiments	- prove
Surveys	- describe
Grounded Theory	- explore

25

Research Method Example

Suppose my Research was about looking at the trustworthiness of computer users in a situation where personal data is being handled such as Youth courts.

Here we are trying to explore trustworthiness and the scale is large and the data is very sensitive in terms of accuracy, potential loss or improper disclosure.

I decide therefore that I need an exploratory study here just to try to identify key Points and ideas. This makes me think of Vignettes.

Vignettes are like tiny case studies that just illustrate ONE important point at a time so a collection of these would indicate several important points in trustworthiness and those points could then form the basis for a more extensive study or to initiate debate about the problem theme.

26

Vignettes Outline

1. Vignettes are used where actions, motives and judgements are to be explored often in sensitive situations.
2. Vignettes always have a context so make sure you are aware of it.
3. Vignettes are essentially qualitative in nature.
4. Useful when the research question starts with 'how' or 'why' and there is a desire to explore and describe some activity or phenomena.
5. You cannot control and indeed have no desire to control the events being looked at but the events should be contemporary.
6. Vignettes enable participants to define the situation in their own terms or for their needs.
7. Most vignettes are "one off" events and as such act as indicators of an idea rather than as some sort of proof of concept.

27

Data Collection Protocol

It is very easy to become confused between a Research Method and a Data Collection Protocol.

What is the difference between a survey and a questionnaire?

A Research Method is a framework that surrounds the whole research design

A Data Collection Protocol is a process for actually collecting the defined data from appropriate sample points

Possible Protocols - interview, questionnaire, observation, role playing, seminars, focus groups, document searching and so on

28

Data Collection Protocol

Vehicle – the mechanism employed by the researcher: interview, questionnaire, observation, role playing, seminar, focus groups, etc

Recording Profile – data will be recording: written report/transcripts, formatted record sheets, video, sound recording, computer logging, excerpts from documents and so on.

Sample criteria – a profile used by the researcher to identify a valid sample point from which data is collected. For example, if we wanted data on business uses of Digital Paper we need a profile of who we should ask for that information. Without a profile we may not have any consistency in our data and it may therefore be meaningless.

29

Data Collection Protocol

Location – this is just a definition of where or from whom you will get the data

Permission – you have to feel certain that the information you seek is legitimately available to you.

Ethical Profile – you need to be clear as to what you are doing, the way you are doing it and what you are asking for is ethically acceptable. Two things are at stake: the results may be biased and the results may not be acceptable.

30

Research Design

Structure – It has two phases: data collection and data processing

Purpose – It has ONE purpose and that is to generate the intended project outcome by using the collected primary data. If it does not do this it is effectively worthless

Means – the Research Design achieves its purpose by defining two essential processes: a process to collect the primary data and a process to transform the primary data into the intended outcome.

An Input/output process
Primary Data → Use Research Design → Outcome

Objects – we need a collection of primary data and also one often uses other secondary data and technical sources to deal with both these processes

31

Phase 1 – Core Idea

Recall – my problem was unsuitable download behaviours, my target is worker productivity and my outcome is a policy document.

BAGeD: This means Basic Activity for Generation Data. It is the core of the Primary Data collection phase and effectively points to the data you need.

Think of the BAGeD as something like a spotlight that you turn on so that only the data that you need is illuminated.

Suppose my BAGeD is based on describing (basic activity) unsuitable user behaviours (the data spotlight) with regard to the Internet and downloads.

Do not get confused here the BAGeD is about describing the data it is not about where the data is or how it might be collected

32

Phase 1 – Complete Process

I prepare by making a list (e.g. from journals or books) of what I regard as unsuitable download behaviours which I use to guide me as I interview staff about what they do on the Internet. Every time I hear about a bad behaviour I make a note so I end up with a collection of bad behaviour incidents descriptions all embedded in my transcripts.

Now some of these incidents will be the ones on my initial list, some will be ones that I never thought of and some on my list may actually never occur - that is why I have to do the interview to get that data collection.

At the end of this first processing phase I have a collection of primary data in the form download behaviour incident description extracted from in transcripts

Now that I have a processing plan I go through the all the steps:

Define the data (BAGeD), Protocol, Locate the data and lastly Collect the data

33

Phase 2 – Pre-Processing

In this study I have my data embedded in interview transcripts so to be efficient I must extract my essential Primary Data from the transcripts

Thinking – before I define my pre-processing I think a lot about what I want as an outcome to make sure that the data set that goes into the last phase is in a suitable form

Pre-Processing – I use my list of bad behaviours definitions and I go through each transcript extracting distinct behaviour incident descriptions to which I attach a name. I present this primary data collection as a catalogue expressed as a matrix of incident names, a short description, location and original user type.

Intension – to get a well-structured primary data collection that is in a form that is useful to me in generating my intended outcome

34

Phase 2 – Process the Collection of Data

My second phase of processing is to take the collection of Primary Data and transform it into a policy which was my expected form of outcome

Process – Using the incident catalogue I derive a policy statement that would prevent or at least put limits on download behaviours.

Implicit in this last phase is that I have the understanding and skill to construct a policy. If I did not then it would be necessary for me to gain the necessary knowledge and skill before attempting that part of the research design.

35

Phase 2 – Process Skill

Example - the University has a policy on assessment and that controls and limits what departments may do. A policy is most often accompanied by a strategy to deal with various aspects of the policy.

Policy - an expression of a prudent mechanism for controlling or limiting actions based on an underlying ethic as expressed in the mission. Structure: PLOT

P - Principles that are based on organisational values or on legislative or contractual elements

L - Links to other policies or documentary sources. If you are not careful you will find yourself overwriting or changing other policies instead of referring to them.

O - Definitions of the objects to be controlled

T - Track or monitoring elements that set limits on what is permissible. This element will form the bulk of the policy definitions

Phase 2 – Process Skill

Therefore the construction process for the download policy is:

- (P) Set out the principles involved (eg. limiting access, etc)
- (L) Make sure you are aware of any other related or relevant policies, legislative or contractual elements or standard formats (eg. Security policy, etc)
- (O) Defining the object to be controlled (e.g the internet, software resources, etc)
- (T) Set up how they are to be tracked and monitored (eg. Software audit, etc)

37

Comments on Exploration

Choose just ONE significant problem and ONE outcome.

Be careful with Scope and Scale (setting limits on your work):

Scope – this means selection or choice. For example, here I might choose to only implement Call Tracking. The point is I set my scope by being selective.

Scale – the means number or extent. For example if I set my scope as looking at Call Tracking I now need to set the number of types of call I will include in my study.

38

Common Errors in the Aim

Poor English – this often makes it near impossible to work out what the student is saying.

Confusion over Outcome and Target – the core element in the aim is the project outcome but it can also contain the target but it must be clear from the way one writes the aim what the outcome is and what the target is.

Operational Outcome – it is very common to see students focusing entirely on the target and omitting the outcome - such as "To generate improved accuracy in data entry to system XYZ" - no outcome and instead we only have the target.

Multiple Activities and Outcomes - there does seem to be an inclination in some students to cram everything into the aim as if they are some kind of superman. The recommendation is to have just ONE clear activity mentioned in the aim and that should be accompanied by a just ONE clear outcome for the aim.

39

Constructing an Aim

Target – what is to be achieved in the real world

Activity – what are you going to do to achieve the aim?

Spotlight – what is the data focus of the activity?

Outcome – what project outcome is wanted?

Example Aim – to create a website structure design using cascading style sheets in order that it might be used in design to improve web site accessibility.

Activity = create, Spotlight = cascading style sheets, Target = to improve accessibility, Outcome = web site structure design.

40

Sample Aim 1

Sample Aim 1 – "To create an improved network infrastructure".

This is unsatisfactory because we have no target - we know that there will be an improved infrastructure but we don't know what effects that will have.

So is improved infrastructure the outcome – it cannot be because it would imply sending to Portsmouth for marking some object called "improved infrastructure" and that is an absurdity.

So here we have no target and no outcome and we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

41

Sample Aim 2

Sample Aim 2 – "To build a Wi-Fi implementation strategy".

This is unsatisfactory because although we know the project outcome is (implementation strategy) we do not know what value it has in the real world because we have no target.

Notice also we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

42

Features of Objectives

- Progressive** – the objectives must sequentially build to the aim
- Activity** – what are you going to do
- Spotlight** – what is the data focus of the activity
- Outcome** – what is the outcome of the activity
- Bounded** – achievable within the project period

Example – To model and document the software development process.

Activity = model, **Spotlight** = software development process, **Outcome** = a document, **Bounded** – yes we can do this in the project period (we cannot show progression as that only applies to the complete collection of objectives)

43

Aim/Objectives - Checks & Balances

Many students get muddled with objectives and one source of this is that often they cannot distinguish between a project objectives (ones that are related to what a student does) and an operational one (things that happen in the real world).

Every time you write an objective you have to ask three questions about it:

- Can Justify** – does the objective make sense in that it generates a minor outcome
- Can Observe** – Make sure that someone else can observe or check what you have done so minor outcome must be in words, diagrams, charts, graphs etc)
- Can Build** – Make sure that YOU can build the outcome stated.

44

Objective Examples

Aim = To report on how the bicycle is an aid to mobility in a modern urban environment

Sample Objective 1 – “To list in a report the components of a modern bicycle”.

This is fine and clearly it is something that you in a project document could do and Somebody else could check it.

Sample Objective 2 – “To describe how a bicycle functions”.

This is no good since although it is clear that you can develop a description no one can check it. Better to say “To describe by means of annotated diagrams how a bicycle functions”

45

Objective Examples

Sample Objective 3 – “To understand how a bicycle helps urban workers”.

This is no good because although you can do it no one else can check it. Better to say “To prepare a report explaining how urban workers could be helped by use of the bicycle”

Sample Objective 4 – “To ensure that workers get to their office in time by using a bicycle”.

This is no good because you cannot do that and if you cannot do it no one can check it. Better to say “To report on bicycle usage strategies that might be applied by urban workers to ensure they get to work on time”.

46

Objective Examples

Sample Objective 5 – “To implement a bicycle repair system”

This is no good since you can clearly do it but it cannot be checked in your project document. Better to say “Report on the implementation of a bicycle repair system” or “Produce a design document for the creation of a bicycle repair centre”

Sample Objective 6 – “To ensure that bicycles conform to BS 7898”.

This is not really much good as it is in essence a requirement and not something that one can do within a project itself. However, one might have written “To prepare a report showing how a bicycle can be evaluated for BS 7898 compliance”.

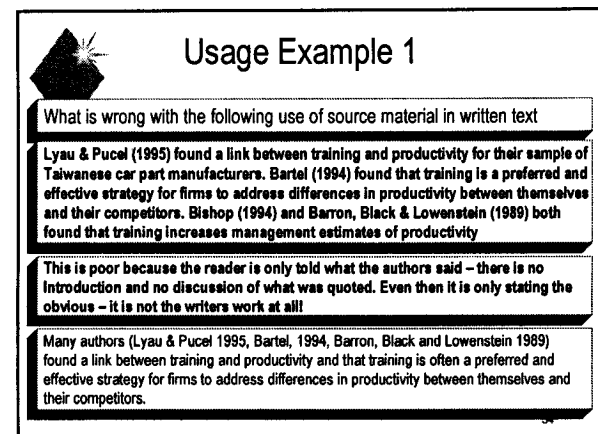

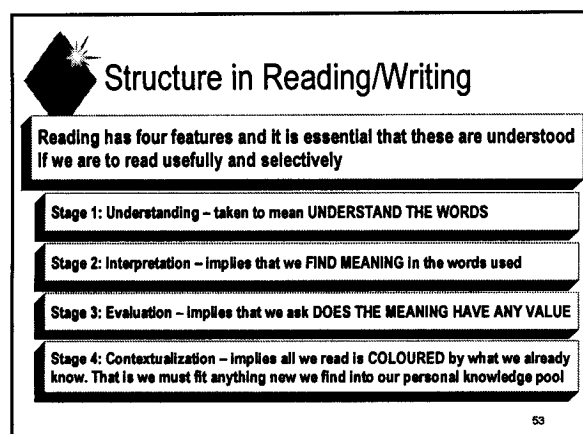

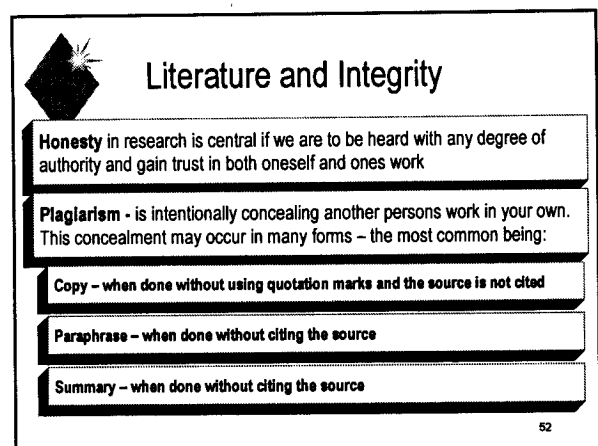

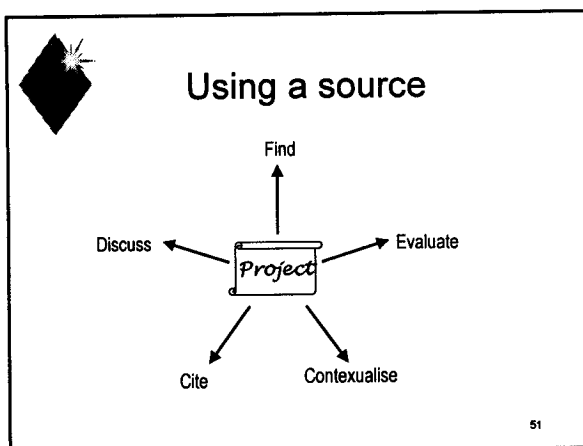

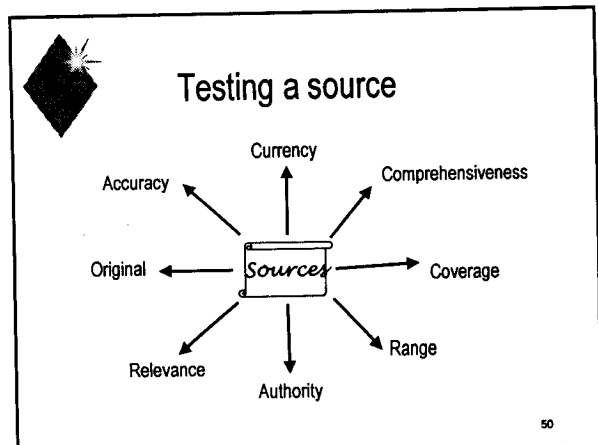

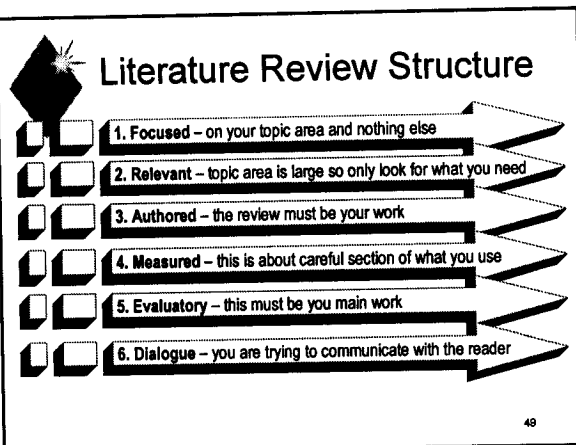

47

Literature Review

Literature Review – this is where one prepares the mind with all the necessary project area knowledge, understanding and skills. (see WB section 5.7.2)

- 1. List** – the various topic strands that have to be learned
- 2. Arrange** – topic list into a logical and progressive order
- 3. Theme** – decide on a theme to link topic strands
- 4. References & Bibliography** – use Harvard APA for this

48

Usage Example 2

What is wrong with the following use of source material in the written text

It has been found that because Arabic words were written by copyists who did not use vowels, over time the meaning of some words has been lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. One way to deal with this is to use assonance and in this paper that approach will be taken (Noldeke 2003, p45).

The problem is that something in the paragraph is attributed to Noldeke - but a reader does not know what that might be. Similarly, a reader can have no idea which part of the paragraph was written by the author of the text or maybe none of it was and it's a paraphrase. This is very bad practice and some tutors even regard it as blatant plagiarism.

55

Correct Usage Example

There is a long standing problems with early Arabic manuscripts in that the meaning of many words has become obscure and even in places where the context is strong their meaning is still unclear [my introduction]. Bigly and Ahmed (1978, p340) and others have shown conclusively that because Arabic words were often written by copyists who did not use vowels, over time the meaning of some words has been lost [a paraphrase]. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding the meaning of some words [my discussion]. It has been usefully suggested by Noldeke (2003,p87) that one way to deal with this is to use "assonance or word ending analysis" [a direct quote] to study words and in this paper that approach will be taken and in particular we will look at some early Arabic poems by Averroes [my discussion again].

56

Usage Example 3

What is wrong with the following use of source material in the written text

St. Clair-Tisdall (1994, p45) said in his seminal paper on Organisation Synergy that "change in organisations is an inevitable consequence of growth" - this is an interesting observation and implies continuous IT progression and updating. Knowing this we can support Briggs (1999, p23) who said that OO is now routinely used in the computing industry.

This is poor because the first statement by St. Clair-Tisdall is clearly obvious and that by Briggs is common knowledge. The point is that using citations here is unnecessary and therefore worthless.

It is obvious change in organisations is an inevitable consequence of growth and in the modern world that must imply continuous IT progression and updating. Many authors, notably St Clair-Tisdall and Briggs have commented on how these naturally progressive elements may be factored into a company sales policy and

Usage Example 4

Explain what the following section found in student work means

It is argued that tactness, complexity, and specificity in a company's skills and resources can generate causal ambiguity in competency-based advantage, and thus raise barriers to imitation (Fahey, 1989). This is to rise a company's distinctive strategic positioning so as to possess some form of sustainable competitive advantage.

If we cannot understand what it is you are saying, then we cannot give you any marks. The sentences are obviously copied, no student would write with such obscure academic complexity - this are not designed to communicate, it is designed to impress other academics.

What it is saying is that some skills are very difficult to duplicate and this may mean that growth may be restricted or if you like it's not all that easy to copy a skill.

Literature Usage

Only quote, paraphrase or summarise when it is necessary and it is not common knowledge and it is not an obvious observation

Common Knowledge: ... Briggs (1999, p23) said that OO is now routinely used in the computing industry

Obvious Observation: ... St. Clair-Tisdall (1994, p45) said that change in organisations is an inevitable consequence of growth

59

Literature Usage

The literature is used to supplement you work, demonstrate your mastery of the topic area and lend authority to what you are saying by building on and learning from other peoples ideas.

Mastery of the topic area does not mean you quote, paraphrase or summarise everything you see or know.

Writing is a form argument and should only be seriously attempted when you are knowledgeable, the argument is essential and you have deep respect for your readers

60

Project Supervision

Monitor Progress on a weekly basis

Advise on methods and matters of fact

Discuss any and all project elements

Read and comment on finished sections

Pose Questions regarding the student's work

Where necessary advise that the work is NOT ready for submission

61

Some Questions

- If students get good marks and pass who should be praised?
- If students get poor marks and fail who should be blamed?
- If a student can recite what they have learned: are they knowledgeable?
- If a student gets 100% do they know almost everything?
- If a student gets 0% do they know nothing?
- What is the function of criticism/feedback on student work?

Learning is about your Thinking, Questioning & Practicing

1

What is knowledge?

- How do you know when anyone has knowledge?
- Knowledge may be simple (recall) or tacit (skill)
- He/she can reproduce it for you to see
- He/she can apply it in a given situation (problem solving)
- He/she can make generalizations from it
- He/she can generate new knowledge from it
- He/she knows knowledge is new, added to, modified or discarded.
- He/she welcomes criticism and regards it as essential to learning

2

An Example

Primary Data Definition - is new data in the sense that it will not exist as a collection until you define, collect and record it. But it must be collected for a specific purpose in that the primary data collection is representative of some aspect of the area under investigation and can be processed to get a defined form of outcome that will resolve or partially resolve a stated problem theme.

Exercise - Suppose I want to define all the various accounting functions so I pick up a manual for my in-house accounting system and then go through it looking for all the various accounting functions and listing them - is that primary data and is this a valid research purpose?

How can we know we understand

- All real knowledge is essentially tacit (a skill)
- One can only demonstrate knowledge by using it not reciting it

4

Critical Thinking

Much of our thinking, left to itself, is biased, distorted, partial, uninformed or down-right prejudiced. Yet the quality of our life and that of what we produce, make, or build depends precisely on the quality of our thought.

Shoddy thinking is costly, both in money and in quality of life.

Excellence in thought, however, must be systematically cultivated.

A Definition - Critical thinking is a process by which the thinker improves the quality of his or her thinking by skillfully taking charge of the structures inherent in thinking and imposing intellectual standards upon them.

The Result - A well cultivated critical thinker

5

Weltanschauung

- Your personal world view is rough translation?
- It also has a hint of the idea of motive - why we do or think something?
- Suppose I have a problem of poor student work - speculate about possible causes and ask why you selected that cause?

Is enough feedback
reference material.
Knowledge.
No

6

politics
 ③ viewpoint
 ④ Influence
 ⑤ Religion
 ⑥ UAE (culture)

Weltanschauung why you think as you do

- Your culture and upbringing?
- Your religion or politics?
- The particular viewpoint you take?
- Influence of your teachers?
- Influences of what you read and hear?
- Ignorance?

Thinking Barrier - Culture

Culture - this can get in the way because it tends to have norms

Western - characterized by the notion of free speech and openness so I feel free to be critical of myself, my wife, religion, politics, the weather, the Vicar, the prime minister, the Bible, the Qu'ran, the Gita, etc.

Rationale - A society or an individual that limits such freedoms is ultimately self-destructive because it's as if there is nothing new to learn, nothing can be reinterpreted, nothing can be enhanced, nothing discarded as no longer valid and so no new thoughts and ideas are possible.

Eastern & Asian - characterized by a relatively closed society with a huge concern for what is right and a sense of uneasiness about criticism of almost anything but personal things in particular.

Rationale - society should be ordered, there is always a right way of doing things and respect is a dominant quality.

Culture - What can we do about it?

Nothing since it almost totally defines who we are

Awareness - we cannot and mostly do not want to get rid of our culture but we can become aware of it and how it influences and dictates the way we think and act and in that way it can become as a moderator for us.

Arrogance - sometimes our cultural heritage can make us arrogant so we will NOT accept that we might be wrong - so we stop listening and instead we keep repeating what we have already been told might not be right in some arrogant hope that someone will eventually comfort us by saying we were right

Thinking Barriers - Ignorance

Reading - we often do not read widely and sometimes not at all. This means our mind is not being continually stimulated.

Challenge - when we read widely our minds are challenged by new ideas

Argument - reading builds up our knowledge and makes us rational

Discussion - ideas can be used in discussion and communication

Possibilities - reading open our minds to new ideas and old ones

Pleasure - the process is pleasurable in itself

RCADP

What a Critical Thinker Does

- Problems - formulating them clearly and precisely as a starting point
- Open Minded - thinks about alternative systems of thought, recognizing and assessing their underlying assumptions, implications, and practical consequences
- Form of Answer - what sort of answer is one looking for to given questions
- Criticism - accepts and actively seeks criticism as essential to his work
- Data - Gathers/assess relevant information, using abstract ideas to interpret it
- Processing - comes to well-reasoned conclusions and solutions, testing them against relevant criteria and standards
- Communicates - with others looking for solutions to complex problems

What a Critical Thinking Is/Needs

What it is

- Self-directed
- Self-directed
- Self-monitored
- Self-corrected

What it requires

- Excellence
- Communication
- Problem Solving
- Not Egocentric
- Not Sociocentric

ECPEs

CEPA

Some Exercises

Try to form a definition of the term problem itself?

A critical situation which requires a need to a solution

How many ways can we define to solve problems?

How is your problem solving ability affected by your weltanschauung?

13

What is a problem?

[Bryant 1989] problems are situations where circumstances confound action and doubt clouds decision

[Reitman 1965] proposed a categorisation of problems based on how well one could specify each of two terminal states.

[Simon 1985] proposed that a human being is confronted with a problem when he has accepted a task but does not know how to carry it out.

[Checkland 1989] a problem is a matter of concern or debate among situation actors

[Mayer 1983] a problem is a differences in two states and one wants to get from one state to the other.

14

Only 5 ways?

Trial and Error (T) - the process is akin to guessing and chance is at work and therefore problem solving may or may not take place.

Top Down (D) - the classical idea of divide and conquer - a complex problem is resolved into smaller and therefore simpler problems.

Generic Solutions (G) - using previous experience. This is a productive mechanism since we ask have we seen something like this before.

View Points (V) - if we have a clear idea of what view we have then we change our viewpoint so that we see the same problem in another light.

Relationships (R) - we consider how elements affect and are affected by other elements. This tends to be the deepest level of solution.

15

Two Application Methods

You can apply the strategies in sequence: {T,G} meaning do T then afterwards do G

You can apply the strategies in parallel: {T,G} meaning do T and G at the same time

You can do all this on your own or with other people

16

What is going on here?

Think of teaching a programming language as a problem. We could adopt either strategy a and b - now say what problem solving technique or techniques is being used in each one putting yourself first as the teacher and then as the student (what does it look like from a given perspective)

a. Teach in detail appropriate language constructs and gradually show how complete programs might be built.

b. Discuss whole programs and how program elements hang together, learning appropriate language constructs as they are needed.

17

What is going on here?

Brainstorming a problem is the recording of the rapid and free expression of thoughts about the problem and possible solutions. Brainstorming is carried out in three phases.

Generate - Ideas at random and in quick succession for a set period of time

Group - examine all the generated ideas and put them into a number of suitable categories or themes

Grade - finally the ideas are evaluated and ranked in order of importance in relation to the problem setting.

Examine this structure and see if you can write it down using a combination of the 5 strategies (T,D,G,V and R)

18

Learning – What is it?

Think about the following two questions:

1. What is the colour of your shirt?
2. Describe why this course will fit you for work in the modern computer industry or in business IT

Analysis
Synthesis
Evaluation

design

ASE

19

Learning – Can I do it?

Memorizing?
Understanding?
Reflection (Ijtihad or Taqlid)?
Problem Solving?
Finding Meaning?
Contextualization?

20

Two Ideas Poles Apart

Ijtihad – this means something like the idea of critical reflection in English but it has the added nuance of the idea of struggle (from the root jihad).

Why a Struggle – not so much because we might learn new things but those new things might mean you may have to modify what you thought was solid, you may have to find a new interpretation, and you may have to throw away altogether some things and start again – if you think about that for a minute you will realize there is considerable struggle implied.

21

Two Ideas Poles Apart

Taqlid - this means something like blind unquestioning obedience to what you have been taught – it's as if nothing at all can be added either as ideas or interpretation.

In practice all we would be doing if we take this view is simply regurgitating what others have said and using the same methods over and over again and never moving forward. It's as if the idea of new knowledge itself has been discontinued, that we already know all there is to know.

22

How to Think

The prophet Mohammed in a Hadith is reported to have been asked the following question:

Question: Is it permitted to have doubts?

Answer:

Creative Doubt
Self-critical
Ask Questions
Challenge
Discuss
Reflection (Ijtihad)
Honesty

23

Skills Allied to Thinking

Read
Write
Speak
Listen

24

Thinking means Questioning

Bi-polar Questions – those with a limited range of answers

Is it possible to sharpen this pencil? (Y/N)
What is the correct pencil weight for drawing a picture? (HB1, HB2 etc)

25

Thinking means Questioning

Open Questions – give liberty to provide various forms of answer

Explanation: question expects an answer as a process/procedure

How can a pencil be sharpened safely by young children?

Description: answer expressed as a description or an evaluation

What is the purpose of HB0 pencils? (simple description)
Why are HB0 pencils difficult to sharpen? (an evaluation)

Exploration: answer in the form of a discussion

How should we use HB1 pencils best in drawing figures? (often an exploration is needed here leading to an explanation)

26

Dogma – what is it?

This simply means things you have to take at face value. Most often dogma is presented in such a way that one is not allowed to question it.

start from Dogma = The Truth

Religious Dogma – about heaven, hell, sin, what you can wear, eat, etc

Political Dogma – what is best for you, what is best for the country etc

Market Dogma – globalization, economics, trade, free markets, etc

Academic Dogma – theories, methods, tools, ideas etc

27

What is Thinking?

Some words from the Bible – Jesus said "If what you see causes you to sin, tear your eyes out and fling them away"

1. Can you understand these words?

2. If you can understand them what do they mean?

Ibn Rushd said - if the literal meaning of the words is clear but don't make sense the writer must have meant something else so we must find the meaning of the words

28

Dogma – what is its effect?

It tends to stop you thinking and questioning

Question – be honest with yourself and think about what you do when you see, hear or read something which is at odds with what you know or believe be it religious, political, academic or whatever?

The trouble with dogma is that it tends to make your rational mind BLIND

When a blind rationality sees, hears or reads something which is at odds with what it knows or believe the reaction is not to ask what does it mean BUT to blindly say it must be wrong

The Data is Wrong – students often come to me and say my data is wrong. What they mean is it gives them an answer that they don't like.

29

Dogma – what can we do?

Is Dogma therefore good, bad or neutral?

Can we stop people believing in something?

Learn to react in a listening manner so think for yourself

Learn to rationally question contrary opinion

Ask for and examine the evidence

Learn to be open-minded – accept for what they are other people views

Don't be afraid to disagree – but do it rationally if you can

Be aware of our own bias and prejudice

Accept that what you thought was truth might need to be changed

30

Dogma – what can we do?

- Listen to their teachers (notice it does not say agree with them)
- Listen to anyone (notice it does not say agree with them)
- Aware of ones own bias and prejudice
- Discuss freely without rancor
- Appreciate other points of view
- Be aware of the influence of ones own culture

31

A Student's Duty

- To continually ask questions of their teachers
- To continually ask questions about what one reads, sees or hears
- To challenge their teachers ideas and opinions
- To stop thinking that always there is a right answer
- To believe that there may be best answers
- To question what your own thinking
- To welcome criticism and not to look always for praise

32

An Anecdote

Good teachers are not enough YOU must find the best way for YOU to learn.

Imam Al-Ghazali went to University in Gurgan. He studied there for 4 years covering several subjects – indeed everything that could be learned there.

On his way back his caravan was attacked by Bedouins who took everything including all his course notes which were in a leather bag.

He begged the Bedouin chief to give him the notes as they were no use to anybody but him and in any case the Bedouin could neither read nor write.

The Bedouin then threw the bag of notes at Al-Ghazali and said "I thought you went to University to learn, not to take notes!"

Al-Ghazali was so struck by this idea that he went back to Gurgan for 4 more years, took no notes but thought a great deal and became one of the foremost scholars of his age or perhaps any age.

What Tutors do

- When asked a question try to avoid giving the answer directly
- Answer a question by asking another question
- Answer a question by asking students to do something
- Answer a question by offering several answers
- Answer a question by discussing its context

34

Challenging Students

- Answer a question by asking them to guess the answer
- Answer a question by asking if they can find a simplification
- Answer a question by asking if they have seen a similar problem before
- Answer a question by asking if they can find a different view of the problem
- Answer a question by asking if they can find any links within the problem
- Eventually the students will do all of the above to themselves

35

What is a Learning Community?

36

Speculation = Theory

Proposal Summary

Title – must be well specified and relevant

Problem Setting – this is the setting or background to your problem

Presenting Problem Definition – definition of a single significant problem

Real-World Target – this is a description of desirable real world effects

Research Question – constructed by linking the 5 SPITS elements

Intended Project Outcome – the object that will be used to generate the target

Design for Collecting Primary Data – data definition and collection process

Design for Processing Primary Data – process details to get the outcome from the primary data

1

vignettes = example

Que

Proposal Example 1

Title – Enhancing IT performance - an accelerator to post-merger integration

Problem Setting – ABC Media Group Plc is the result of a recent merger, making it the largest commercial broadcaster in the UK. IT performance is viewed as critical to the success of the new company and since several companies are involved it is important to merge business functions, processes and so reduce resource duplication which all assist cost saving.

Presenting Problem Definition – Post Merger Integration is crucial success element in any given merger because it enables common business processes and economies of scale. IT underpins most critical business processes and the system integration process and infrastructures will accelerate or delay the overall business merger.

2

*what I do (Explore, Build)
Smart interviews*

a research method ~~protocol~~

case study
Survey
Interview
Observation
Seminar

many collection protocols
away of collecting data
Questionnaire

Target - A reduction in the timescale needed to integrate IT in a post-merger environment, allowing a company to achieve cost and efficiency benefits soonest.

Outcome - A documented standard model for the planning and implementation of a merger based IT integration process.

Research Question - How can (interrogative) IT performance of disparate systems (problem) be enhanced to accelerate the process of post merger integration (target) by examining the system integration process (spotlight) in order to define an IT integration model for planning and implementation. (Suggested outcome).

Design for Collecting Primary Data - The key activity here is to identify and explore IT integration activities performed and decisions made by individuals and groups in a pre-merger situation and post-merger reviews. To fully explore the decision making process and explain actions there will need to be interactive elements to primary data collection. Therefore a mixture of semi-structured and in-depth interviews coupled with document analysis.

No important in Order

Sept 21/22

(What you need)
define (Which)
where is the data
How to collect

Where

define
Locate
Collect
Recover

fully understand the past flow
How to Record the data < audio

Design for Processing Primary Data - Here I am looking to eventually produce a model for the IT planning and integration process so I will use the usual model idea of linking activities and processes. Given this, the data may best be interpreted with the aid of tools from Soft Systems Methodology starting with a Rich Pictures to aid with understanding, interpretation and the sharing of perceptions on of specific events. From this we may use the basic SSM tools of Relevant Systems and Root Definitions and hence move to the conceptual modelling stage and then on to...

Summary of what we will do

- Define - Problem and associated target
- Research Question - at a minimum linking problem and target
- Outcome - the object to be generated: model, report, theory, a matrix,....
- Aim - to link outcome and target
- Objectives - a set of activities that generate minor project outcomes
- Research Design Part 1 - define the data and state how it is to be collected
- Research Design Part 2 - process the collected primary data to get the outcome

Basic Research Structure

- Topic Area - this just define the general area in which you are working this is a simple step and although part of the process is not a key elements in focusing
- Problem - define a single significant problem
- Target - say what real-world effects will be produced if we can solve the problem
- Outcome - what is it that you can produce that will generate the target effects

Cyclic Research Structure

Handwritten notes: "target verb" with an arrow pointing to the Target box, and "outcome produce" with an arrow pointing to the Outcome box.

An Important Distinction

- Problem - is something that is a matter of concern or debate in a given situation
- Target - this is the real-world effect that you want to produce. It might be things like: Improved network infrastructure, strategic Technology alignment, reduce network down time, a heightened awareness of security etc. (VERBS)
- Outcome - this is what you produce as part of your project, dissertation or thesis. As we have seen the idea is that we can use this outcome to generate the target effects. Possible outcomes are: a model, an explanation of some behavior, a usage protocol, a feasibility report, a post implementation review etc (Nouns)
- Features of an outcome - when you name your outcome ask: can I write it down, is it easily observable, can it be placed in a document, can it be sent to Portsmouth for marking. If it is any or all of these its probably an outcome

Can I define a problem?

Example 1 - My problem is to find a way to implement a new network infrastructure"

I might reword this as "my problem is to find an answer" - I think you will agree that such a formulation is worthless."

It is better to start off with a problem idea such as uncertainties associated with the technology needed for the proposed new network infrastructure.

Example 2 - My problem is lack of IT training in the help desk staff

This is hopeless because in fact it is a solution not a problem. It is obvious that if the problem is lack of training the solution is to give training so for all practical purposes that sort of formulation is worthless

Much better to say, in this case, that the problem is complaints about help desk operation from customers.

Can I define a problem?

Example 3 - My problem is to decide if a training policy can be constructed to deal with the data entry errors in our CRM system

Its so obvious really that you may miss it - "decide can be .." well of course this CAN be done so its not much of a problem is it if we already know the answer. In effect the student is saying his problem is to know if there is solution.

The problem is data entry errors and that is what needs to be analyzed

Handwritten notes: "decide/can be" and "avoid close question."

Here are the most common faults we see when we look at problem definitions

Listing many problems,
 Stating the problem as something to do,
 Stating the problem as being something is missing
 Stating a solution not a problem,
 Stating the problem is the problem
 Trivial problems,
 Non strategic business IT problems,
 Not stating a problem at all.

Can you make the Distinction

1. A strategy
2. Increased productivity
3. Better fit with technology
4. A best Practice Model
5. Improved sales
6. A security policy
7. Highly usable systems
8. Efficient network control
9. A pattern of work
10. A process flow
11. Simpler Web Page Access
12. A role description
13. Better trained operators
14. A list

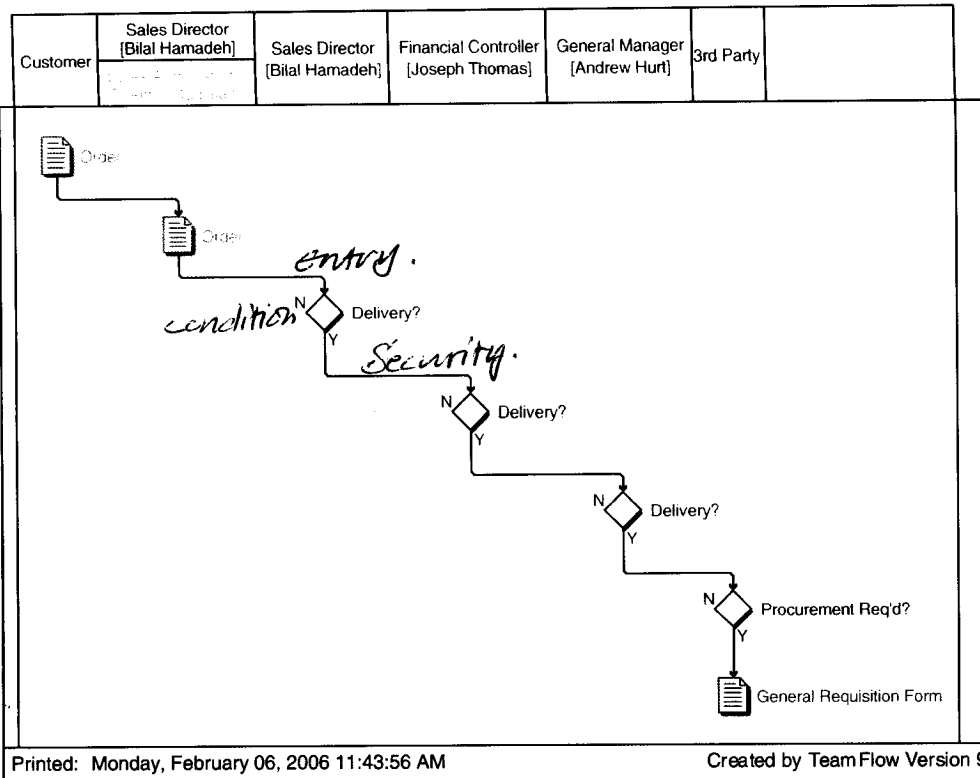

15. A theory
16. A feasibility report
17. A computerised sales program
18. A post implementation review
19. A predicative report
20. A process description
21. A model or framework description
22. Improve IT management
23. A definition or set of definitions
24. A comparison matrix
25. A design
26. A methodology
27. A security protocol
28. Secure passwords

I. Title: Document Management Strategies

II. Background: Managing documents is important for any organization. Every company has its own document storage and retrieval systems. A document management system (DMS) is a set of computer programs to track and store electronic documents and images. Document management systems basically provide storage, security, metadata, versioning as well as indexing and retrieval capabilities. DMS is increasingly being used in UAE both in private as well as government sector. e-Tawasul-Document Management system of UAE e-government is one such example.

III. Presenting Problem Definition: Despite being time, space consuming and expensive to maintain, use of traditional DMS still persists. Adopting proper document management strategy is therefore very important. DMS has far more potential than merely reducing paper work. Organizations in UAE need proper DMS strategies to efficiently track and store documents.

III. Real World Target: Inform UAE companies about the advantages of an efficient DMS. The reduced time for data retrieval, storage and security can help companies reduce storage, distribution and people costs.

IV. Research Questions: What are the bottlenecks in present DMS in UAE? How can they be overcome? How can they be optimized to reduce storage, distribution and people costs?

V. Personal Theory: DMS is very important for an organization. I believe that DMS can significantly help UAE organizations in storage, retrieval, filing, security, archival, retention, distribution, workflow and creation of documents. DMS can help UAE companies to reduce storage, distribution and people costs.

VI. Intended Project Outcome: The project aims to come up with strategies for efficient document management. It will analyze the reasons for Data Management bottlenecks in UAE organizations and suggest strategies and best practices to overcome them. Proper approach for migrating from a traditional to a modern DMS will also be laid down.

VII. Strategic IT Value: DMS not only helps in cost reduction but also in increased productivity of the employees. UAE Organizations can achieve substantial business benefits like improved customer service, reduced order-processing time, faster internal approvals, improved AR and collections, reduced processing errors and increased business process control by implementing modern DMS strategies.

VIII. Design for Collecting Primary Data: I will analyze bottlenecks and complications in document management processes. It will involve analyzing present document management processes in UAE organizations. I will interview key people in the organizations for collecting primary data.

IX. Design for Processing Primary Data: I will use the collected primary data to analyze reasons behind DMS bottlenecks. I will also evaluate successful approaches adopted in organizations to tackle them. I will then suggest effective strategies for document management.

Literature Review

Document management is a vital function in any organization. Every organization has its own document storage and retrieval systems based on its requirements. Document Management System (DMS) is defined as a set of computer programs to track and store electronic documents and images. Document management systems basically provide storage, security, metadata, versioning as well as indexing and retrieval capabilities.

DMS is increasingly being used in UAE both in private as well as government sector. e-Tawasul-Document Management system of UAE e-government is one such example.

Dubai Land Department has completely digitized its document. It has implemented a DMS from FileNet. The DMS will make its land and property transactions faster (*"Dubai Land"*, 2006).

Key Document Management System (DMS) Areas

Any document management system in a UAE organization needs to address important questions under the following key DMS areas:

Storage: UAE organizations first need to decide where they want to store their documents and the budget they have for their storage.

Retrieval: The next question is how to retrieve the documents and how much time they can spend to search for them.

Filing: How are the documents organized? What steps the organization needs to take to ensure documents are filed appropriately?

Security: How does the organization safeguards itself against loss, tampering and destruction of documents? What mechanism it follows to keep its classified information secure?

Archival: What steps has the organization taken to maintain the readability of its documents in future? What mechanism has it in place to keep its document safe?

Retention: A very important point is to decide which documents to retain and which to discard. What should be the life period of a document and what should be the process to discard it?

Distribution: Getting the document across to people on time is also extremely important. How much can the organization budget for document distribution?

Workflow: How will the flow of documents from one person to another be maintained? What will be the rules to guide the flow?

Creation: Rules on collaboration in the creation of document among staff is equally important.

DMS Components

Document Management System basically comprise of storage, versioning, metadata, security, indexing and retrieval capabilities.

Metadata: Metadata of a document includes information about the date of storage, person saving the document, scanned images or text.

Integration: Integration is done so that users can retrieve existing documents directly from the document management system, make changes, and save the changed document back as a new version.

Capture: Capturing involves the process of using scanners or multifunction printers to take the images of paper documents.

Indexing: Indexing is done to keep track of the documents. It is vital for swift retrieval of the documents. Creation of index topology is an important part of this process.

Storage: Storage of the electronic documents often involves issues like where the documents will be stored, how long will they be stored, when and how will they be transferred from one storage media to another and when will they be finally destroyed.

Retrieval: Retrieval involves finding the stored document from the storage. This may be a simple process for individual documents to more flexible retrieval involving document identifier or meta data.

Other DMS components are **Distribution, Security, Workflow, Collaboration, and Versioning.**

Advantages of DMS

DMS has numerous advantages. UAE organization can implement a lot by investing in DMS. Some of these advantages are as follows:

- 1) DMS helps in cost reduction and increased productivity of the employees. Document management systems eliminate the cost of lost documents
- 2) Organizations can achieve substantial business benefits like improved customer service, reduced order-processing time, faster internal approvals, improved AR and collections, reduced processing errors and increased business process control by implementing modern DMS strategies.
- 3) Document management systems provide several layers of security like password protection, encryption and audit trails.
- 4) DMS help include off-site data backups and other mechanism to save data in the event of a natural disaster.
- 5) DMS allows multiple accesses to the same document.
- 6) DMS helps in ensuring process consistency.

Implementing DMS

A good requirement analysis is important for implementing a document management solution. We need to ask the following questions before choosing a DMS:

- 1) What documents exist?
- 2) Who created them?
- 3) What are they used for?
- 4) Which areas of the organization need document management?
- 5) Which of these documents are confidential?
- 6) What documents need to be retained?
- 7) What technologies can be implemented?
- 8) What is the budget available?

Based on the answers to these questions a Business Requirements document is prepared and this helps in choosing an optimum solution. The process from defining requirements to selecting a solution differs from organization to organization. It also requires discussion with the stakeholders within the organization.

While implementing a DMS several concurrent processes are undertaken. These processes can be summarized as follows:

- 1) The technology implementation process is done through IT department. It involves hardware configuration, installing the operating system and application software components.
- 2) Discussion is done with people in key business areas of the organization. This is done to find out how a task is completed. If required the existing procedures and guidelines are reworked.
- 3) The third process is configuration. It requires sampling business documents and finding what is common in them. Document categories and access level of the document is also defined.
- 4) The fourth process is the most important. It involves people working with the organization. The goal of a successful DMS is to satisfy the end users apart from meeting the management's requirement.

DMS in UAE

UAE organization both in government and private sector are implementing DMS to ensure greater operational efficiency. Implementation of DMS is part of the 'paperless' initiative undertaken by the government and private sector. It is helping in automating, accelerating business processes, boosting efficiency saving costs.

Dubai Municipality (DM) is implementing Enterprise Document Management System (EDMS) in collaboration with IBM and Etisalat. It will help in improving internal and external business processes by creating a single document repository solution (*"Dubai Municipality", 2006*)

Challenges In DMS Implementation

Successful DMS application in UAE faces many challenges. Some of them are technical while others are cultural.

- 1) Resistance to change
- 2) Integration with existing legacy systems
- 3) Scale of the project.

Project Specification

Intention -- This study is focused on laying down DMS strategies for Organizations in UAE. It will inform UAE companies about the advantages of DMS, find bottlenecks in their implementation and suggest strategies to overcome them during implementation.

Project Title - Document Management Strategies

Project Topic Area Overview

Managing documents is important for any organization. Every company has its own document storage and retrieval systems. A document management system (DMS) is a set of computer programs to track and store electronic documents and images. Document management systems basically provide storage, security, metadata, versioning as well as indexing and retrieval capabilities.

DMS is increasingly being used in UAE both in private as well as government sector. e-Tawasul-Document Management system of UAE e-government is one such example.

Dubai Municipality (DM) is implementing Enterprise Document Management System (EDMS) in collaboration with IBM and Etisalat. It will help in improving internal and external business processes by creating a single document repository solution (*"Dubai Municipality", 2006*)

Situation Overview

The study will look at the introduction of DMS in UAE organizations. It will involve interviews with employees of the organizations implementing DMS and consultants from the implementing agencies.

Presenting Problem Definition

Despite being time, space consuming and expensive to maintain, use of traditional DMS still persists. Adopting proper document management strategy is therefore very important. DMS has far more potential than merely reducing paper work. Organizations in UAE need proper DMS strategies to efficiently track and store documents. There are cultural as well as technological challenges to DMS implementation.

Real-World Target

This study will inform UAE organizations about the advantages of an efficient DMS. The reduced time for data retrieval, storage and security can help companies reduce storage, distribution and people costs. It will also help UAE organizations in improving their internal and external business process. The study will suggest strategies for the seamless implementation of DMS in UAE organizations.

Research Question

The study will address several key questions in DMS implementation in UAE. Some of these are:

- 1) What are the bottlenecks in present DMS in UAE?
- 2) How can they be overcome?
- 3) How can they be optimized to reduce storage, distribution and people costs?
- 4) What are the challenges in successful DMS implementation in UAE?
- 5) How each group of involved in DMS implementation perceives it?

Personal Theory

DMS is very important for an organization. I believe that DMS can significantly help UAE organizations in storage, retrieval, filing, security, archival, retention, distribution, workflow and creation of documents. DMS can help UAE companies to reduce storage, distribution and people costs. Successful implementation of DMS involves many challenges and requires addressing several key issues.

Intended Project Outcome

The project aims to come up with strategies for efficient document management system. It will analyze the reasons for Data Management bottlenecks in UAE organizations and suggest strategies and best practices to overcome them. Proper approach for migrating from a traditional to a modern DMS will also be laid down.

Strategic IT Value

DMS not only helps in cost reduction but also in increased productivity of the employees. UAE Organizations can achieve substantial business benefits like improved customer service, reduced order-processing time, faster internal approvals, improved AR and collections, reduced processing errors and increased business process control by implementing modern DMS strategies. Proper DMS implementation will help UAE organizations in improving their internal and external business process.

Ethical Overview

DMS implementation does not raise any ethical questions as it is done for efficient document management in an organization. These DMS have various levels of access to protect classified information.

Aim

The aim of this study is to lay down DMS strategies for Organizations in UAE. It will inform UAE companies about the advantages of DMS, find bottlenecks in their implementation and suggest strategies to overcome them during implementation.

Objectives

- 1) To analyze the implementation of DMS in UAE organizations.
- 2) To convince UAE organizations of the advantages of a modern and well implemented DMS.
- 3) To find out bottlenecks/challenges in successful implementation of DMS in UAE organizations. This will involve conducting interviews with employees, management of the organization where DMS is being implemented as well as the consultants of the company implementing the DMS.
- 4) To suggest ways to overcome these bottlenecks. This will include strategies for successful implementation of DMS, overcoming challenges in DMS implementation based on the primary data collected through interviews.

Research Design - Research Method

This study will be based on interviews with staff, management of the organizations implementing DMS. Employees are directly associated with DMS implementation and their satisfaction is vital to the successful implementation of DMS. Well designed questions will be addressed to a selected group of employees from different business areas of the implementing organizations and management representatives from the organizations. This will also include interviews with consultants of the company implementing the DMS. Two of these DMS implementation under consideration are e-Tawasul-Document Management system of UAE e-government and Enterprise Document Management System (EDMS) of Dubai Municipality. Consultants from the implementing agency IBM will also be interviewed.

Research Design - Phase 1: Primary Data Collection Process

This part of the research design requires construction of a reliable primary data collection mechanism which will be processed into the form of answers expected at a later stage. The questions for the interview will be well designed and will address the key areas of DMS implementation. The questions will be formulated in such a manner that they address the various aspects of the DMS implementation that involve contribution on part of employees, management and consultants. A successful implementation of DMS requires good collaboration between these three groups. These questions will then be put forward to a representative sample comprising of employees, management and consultants from UAE government's e-Tawasul-Document Management system initiative, Enterprise Document Management System (EDMS) initiative of Dubai Municipality and implementing agency IBM.

Basic Activity for Generating Data

Basic activity for generating primary data is to interview employees, management in organizations where DMS is being implemented or has been implemented. Secondly, interviews will also be conducted with the consultants of the implementing agencies to find out their perceptions of the problems in DMS implementation and how they overcame these problems.

Primary Data

This study will ask specific questions to all the three groups of employees, management and consultants who are instrumental in successful DMS application. The answers to these questions will be the primary data for finding bottlenecks in DMS implementation in UAE organizations and the strategies required to counter them.

Location – The sample group for this study will include a representative pool of employees, management and consultants from UAE government's e-Tawasul-Document Management system initiative, Enterprise Document Management System (EDMS) initiative of Dubai Municipality and implementing agency IBM.

Collection Protocols – The data collection will involve interviewing each member of the sample groups. They will be asked questions related to their experience of DMS implementation. There will be questions related to the particular nature and experience of each group in DMS implementation. Employees will be asked specific questions related to their experience of DMS implementation in their organization. Questions like what do they think of DMS implementation, is it going to make their work process better, will it benefit them or their organization, what problems did they face during implementation, how it can be made better will be addressed to them. Management will be asked questions on cost savings, improvement in processes and its benefit to the organization, how did they convince employees about the viability of DMS implementation and how did they manage to elicit their cooperation. Consultants from the implementing agencies will be asked questions related to technological and cultural hurdles they faced, why they suggested a particular solution etc.

Primary Data Collection Presentation

The interview questions for each group and their answers will be available in the project document appendix. These questions and there answers will then be presented in the form of a table. Questions will be presented in rows while answers to each question by the sample group members will be presented in columns.

Research Design - Phase 2: Processing and Presentation

Research Design phase 2 will involve the processing of collected primary data from the interviews to arrive at desired conclusions. This will involve processing the raw data from the interview transcripts. The data will then be presented in graphical format as bar charts. The frequency of answers to each question will represent the bars for that particular question. The bar charts will be analyzed to arrive at the major issues for various groups. This will help in finding out the bottlenecks in DMS implementation in UAE and defining strategies for their successful removal.

Design of Pre-Processing for Primary Data Collection

The replies provided by those interviewed will be extracted from the interview transcripts and then processed. The answers to each question provided by the sample group members will be put together and their frequency calculated. An example of this can be the answer provided by employees about their perception of DMS implementation. Some may reply that it is very important; others may say that it required but not that important while others may reply that it is not required at all. The end result will be the frequency of answers to each option of the questions under consideration

Design for Results Presentation

The data from the first processing round will be presented in the form of bar charts with each bar corresponding to the frequency of answers provided to a question.

Design for Generating the Intended Project Outcome

After the bar charts are ready we can derive conclusions about the DMS implementation challenges in UAE. This will also give us the perspective of each group involved in DMS implementation. Based on this specific strategy for seamless integration of DMS in the organizations will be suggested. Most of the organizations implementing DMS will face common challenges or hurdles. Some of the challenges will be specific to the organization concerned. The suggested strategies will be more about the general problems on cultural and technological barriers to smooth DMS implementation in the organization. The study will also provide suggestions to overcome the specific problems being faced by the two organizations under consideration.

Few major challenges in implementation can be resistance to change, integration with existing legacy systems and scale of the project. These can be tackled by utilizing specialist input from all key business areas, technology providers, and the buy-in and continuous support of the management.

Some the challenges that where encountered during Dubai Land Department DMS implementation included fragmentation of information, slow customer transaction processing time and meeting more stringent regulations (*"Dubai Land"*, 2006).

Logistics and Tools – Resources Required

Logistics required will include a group of three people who will conduct interviews with three groups involving two UAE organizations being studied. Literature review on DMS, its advantages and challenges in its implementation will also be done. This will help in adopting a focused approach to DMS implementation cases under consideration. Literature review will also help in having a theoretical base to DMS implementation and challenges.

Content List for The Project

- Project Specification
- Project Timeline
- Questionnaires
- Interview transcripts
- Basic Information on DMS implementation cases under consideration

Exercise 001a.01q – What is a problem Definition
Do you have a problem definition and it is clear. Just to help you in this exercise here are the most common faults we see in supposed problem definitions and some notes on problem formation with a concluding exercise.

When you have completed the exercise post you answer into the first Tutor: Discussion Question 1 as shown below. But to do this:

1. Do NOT post answers as attachments as it is laborious for any one to extract and looks at it. Post it straight into the message window and then apply a little formatting.
2. Do NOT post any notes that come as part of the exercise. Just post the question and your attempt at an answer.
3. If you wish or you cannot manage to do all the exercise you can just post part of the exercise.

4. Select one or more posts from another student and read their answers and send comments to him/them.
5. Do NOT send your answers to me. In about a week's time I will send out my suggestion as an answer but if you just ignore the exercise and wait for the answer that will be of no value to you and such laziness is certain to end up in a failure because you simply have not done the work.

6. Full records are kept so if we never see any postings from you the panel who look at you work later will draw their own conclusions about your commitment and readiness to start the project phase.
7. The POINT of these exercises is to make sure you really KNOW what you are doing and get the very best result you can. Not doing them is simply a negative reflection on your commitment and can only lead to disappointment.

What is a problem?

This question has always been difficult to answer since the notion of a problem is hard to pin down. As (Bryan 1989) points out 'examination of dictionaries leads to such definitions as "a problem is something to be solved" but then with a tautological unhelpfulness, cross reference you to a definition that states that "a solution is the answer to a problem". Neither of the above explanations is helpful and we might better take the following definitions as more realistic.

[Bryant 1989] problems are situations where circumstances confound action and doubt clouds decision

[Reitman 1965] proposed a categorisation of problems based on how well one could specify each of two terminal states.

[Simon 1985] proposed that a human being is confronted with a problem when he has accepted a task but does not know how to carry it out.

[Checkland 1989] a problem is a matter of concern or debate among situation actors

[Mayer 1983] a problem is a differences in two states and one want to get from one to the other.

I know the solution

In research we often start by stating a FORM of answer (the MSC project outcome) - that is we know for example the outcome of the project will take the FORM of a report but of course at that stage we do not actually have the report and will not have it until we do the actual research.

However, students often write down the problem in such a way that it is an answer or solution to the problem. So for example, if one writes a problem statement as "lack of training" then implicitly that is a solution as well because it is obvious the answer then becomes "provide training". When this happens it is almost certain that the writer is not thinking about the problem at all but is obsessed with a particular solution. In this particular case the real problem might have been "errors in data entry" and one of many possible solutions is training.

If one cannot define the problem with some degree of clarity then other things in the project definition start to fall apart and gradually the idea disintegrates because in essence without a clear problem to solve one has no direction and then the we might recall the aphorism "if one aims at nothing you will probably hit it".

Defining the Problem

Notice, that it is your own definition we are looking for not one you might look up in a book or on the internet (though you might start with that) because there is often little learning value in just copying a definition as far as deepening your own understanding is concerned.

Remember, that any definition one constructs will not be absolute and universally accepted by everyone - but in research this is not a problem as long as the researcher makes it clear what particular definition is being taken. Do not take this process too far and end up with either over-complicated or trivial definitions - they must be thoughtful and comprehensive. So it is recommended you start by thinking about four things where the acronym CAPE is used:

Characteristics - observable features or facets of the problem idea,
Associations - every problem with have links to other situation elements,
Perspective - when a problem is encountered it will always be from a certain perspective
Effects - say what effects ensue in the real world if the problem is not resolved.

Defining the Problem - Example

Let us suppose that a student has identified the problem theme as Phishing. Naturally, the student will be concerned that this is a good idea and would like confirmation of that before expending time on it. One can ask the course tutor, but he/she is not expert in everything so at best one would only get an opinion as a response so how should a researcher proceed. So for Phishing a researcher might note the following:

Characteristics: illegal, intrusive, upsetting, prays on those who trust their fellow man, etc
Associations: email, chat, file sharing, etc.
Perspective: management (but try to look at it from several perspectives as well)
Effects: destroys confidences in the system, may lead to personal or company losses etc

Normally, it takes quite a few attempts before a definition that is lucid and comprehensive is obtained. Remember, the definition must also be useful within your research study - that is, it's no good having a well formed definition that does not offer a sound basis for a research effort.

Exercise 1

Look at each of these simple supposed problem statements from students and say what faults are evident?

1. My problem is many customer complaints, lost of revenue and managerial weakness.

Solution: My problem is lack of IT training.

3. My problem is to find a way to implement a network infrastructure

4. My problem is growth of phone sales in Hong Kong

5. The problem identified in the topic is how to solve the large number of customers' enquiries via internet broadband hotline service once the customers call the hotline centres

① problem in another problem

② Should focus on real problem

Page 3 of 4

Not doing any thing with IT

(Statistics)

The case for simple statistics in strategic business decision making, or Data driven approach to business hypothesis generation

- You are a consultant brought in by an electronics distributor and consumer sales company to identify potential new markets for electronic gadgets
- Specifically, the company wishes to move from 1st generation electronic goods (TVs, VCRs, desktops) to second generation goods (PDAs, laptops, wireless technologies) with a view to addressing the needs of younger consumers who now have greater buying potential than ever before

Imagine...

Data

- The electronics sales company has an extensive database of its customers obtained when customers return post-sales questionnaires to complete the registration of their products
- The company has also purchased from other sources data concerning their customers

Your task

- To examine the data using traditional analytical IT techniques to determine future strategic business planning for the company
- To identify specific customer groups that the company can then target with their products

future strategic business planning
who?
whom are the target.

- Pearson chi-square tests the hypothesis that the row and column variables are independent (not related). The actual value of the statistic isn't very informative.
- The significance value (Asymp. Sig.) has the information we're looking for. The lower the significance value, the less likely it is that the two variables are independent (unrelated).
- In other words, if the relationship is significant, there is some relationship or dependency between the variables

- In this case, the significance value is so low that it is displayed as .000, which means that it would appear that the two variables are, indeed, related.
- You can add a layer variable to create a three-way table in which categories of the row and column variables are further subdivided by categories of the layer variable

- The purpose of a cross-tabulation is to show the relationship (or lack thereof) between two variables.
- Although there appears to be some relationship between the two variables, is there any reason to believe that the differences in PDA ownership is anything different income categories is anything more than random variation?

- A number of tests are available to determine if the relationship between two cross-tabulated variables is significant. One of the more common tests is chi-square.
- One of the advantages of chi-square is that it is appropriate for almost any kind of data.

Let's look at the significance value
 0.000
 → very significant
 ↓ 0.5

Basic search

4. Subject Directory -> Computing & Info'n Science -> Electronic Journals

5. Subject Directory -> Computing & Info'n Science -> Organisations
(only tackle 5 & 6 if time) - usually not!

6. Subject Directory -> Computing & Info'n Science -> Reference Tools

e.g. FEVL

7. Internet Search Tools -> Search Engines & Directories -> Google Scholar

8. Internet Search Tools -> Search Engines & Directories -> Windows Live Academic

Explain nature of Google Scholar and WLA (beta testing, 'sources' not revealed, take care with results).

Referencing

saves time, avoid plagiarism (& punishment), give credit, & look good!

Or talk about this with database record on screen and demonstrate how to fill in the form from the fields on a particular record (plus user details and signing the back)

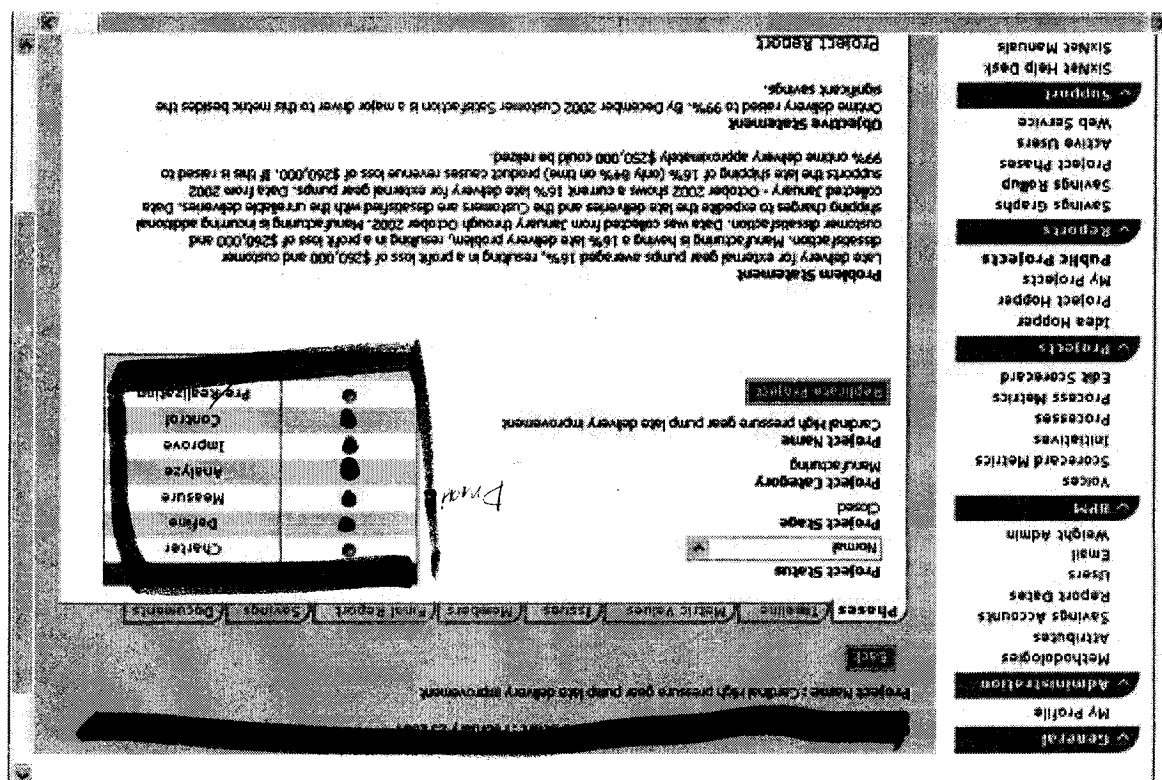

Mindmapping

Explain its utility for generating keywords to be used in searching (as well note taking in lectures, giving a presentation or planning a party!). Demonstrate how mindmap grows as additional keywords are found looking at keywords of database articles whether or not the article is required.

→ sometimes do this at start

& keep developing map through session.

Execution (3D) statistics.

Master Project Topic:

- 78- Document Management Strategies
- 81- Strategic Issues in Document & Information Management
- 82- Developing a Corporate Strategy for Document & Information Management
- 83- Document Management "Support for Critical Business Processes"

Title: Document management "Support for critical business processes."

Problem setting: Our problem is the Document management weaknesses which affects the business in certain ways
Xerox & their business in the use

Presenting Problem definition: (negative impact on the business) ...
Delays in delivery of the product
Rework (multi-task) ...
Cost (Problem field)

Real world TARGET: summarize the whole important impact in 1 or 2 sentences
Reduce the cost & more efficient document control

Research Question:

SPTS :

Spotlight: data flow of the work procedure in the company.
Problem :

Interrogative: How or what

Target: summarize the whole important impact in 1 or 2 sentences
Reduce the cost & more efficient document control

Suggested outcome: implementation plan or rebuilding plan or document plan
New document work flow
Plan to rebuild the current documentation work flow

Solution: Document management (documentum)

Intended project Outcome: *project implementation plan or a plan for managing the*
implementation of document management application (documentum)

There is an **objective** for:

1. The project
2. The document management system (application)

To define a project management structure

Design for collecting primary data : paged describe the current work flow

Or it could be describe the current documentation work practices.

Design for processing primary data : collection of documentation work practices, what I collect is actually what the people are really doing

How you will use this work practices to get the new work flow (outcome)
Apply a methodology to get the outcome

Registration with the university library

Research Methods: Assessment No. 1a – Project Specification and Outline Literature Review

Introduction

The full assessment plan for the Master's programme can be found in Workbook 1 of the workbook pack – you must ensure that you are familiar with it as the work here is only part of the overall plan. In this assessment you develop a short literature review and project specification which is to be approved by a University panel.

You are reminded that this work is weighted and to assess whether you have passed the unit as a whole it will be combined with the statistics assessment in the ratio of 0.7 * Assessment 1a + 0.3 * Assessment 2 where all assessment marks are expressed as a percentage. The overall pass mark is 40%.

Project Focus

The project you write later in the course must be based on the specification you produce here. The project must be coherent with the programme title, therefore, it must be

Research Based – means that you have to collect original data (called primary data) yourself. Primary data is not something you can get out of a book or just download from the internet – it has to be totally original. Whatever you decide with regard to primary data you MUST make sure you can actually get what you say from wherever the data is located.

Strategic Business IT Orientation – the primary data you collect has to be used to generate a Strategic Business IT outcome of some kind.

IT learning – the project must represent significant learning potential in the IT/computing field for you.

Project Style – for this degree only the project style known as "Study" is allowed.

New Work - projects must be new work and you are NOT permitted to use any project material or data that may have been used before on another course or indeed for any other purpose. If it is discovered that previous project work or research material is being re-used it will result in immediate disciplinary action.

Topic Areas

There are no restrictions on choice of topic as long as it can be regarded as Strategic Business IT, however, project ideas in the following areas are very common and unlikely to find acceptance: eBanking, eCommerce, mCommerce, eLearning, IT in Education, Web Site Strategies, Outsourcing, wireless technology and systems, PDA and mobility, simple HCI, Music Distribution, VoIP, HelpDesks, CRM/ERP factors, or simple security/cyber crime. If you feel that you have a novel or new view on any of the above with a hint of originality within a Strategic Business IT framework then you should write to the Research Methods tutor outlining your new idea.

Work Schedule

None of your submitted work will be considered unless you complete the induction check. In addition, you should note that Assessment 1a is made up of 3 parts plus the pre-work. Therefore in summary:

Pre-Work – you must complete the induction checklist (sent to the University managers) and provide a personal profile (see Appendix C) which when ready is sent to Research Methods tutor (Mr Fred Garlick) in a WebCT email. This work must be done by the end of week 3 – if not you work will not be considered for assessment and your registration revoked.

Part 1: Project Approval - Gaining project approval during the first few weeks of the course based on a written outline and this is worth up to 10 marks.

Part 2: Online Tests - Passing the 5 online tests, one of which is set each week for 5 weeks is worth up to 5 marks, one mark for each test passed.

Part 3: Short Literature Review and Project Specification - This is the main Assessment and consists of a short Literature Review and your MSc project specification and is worth up to 85 marks – the mark distribution is discussed later in this document.

Format and Word Limit - The Short Literature Review and MSc Project Specification must not exceed 2,500 words (including the headings) but excluding the reference list and project plan. In the specification if any major headings are missing, any headings are altered, the sequence of headings changed or any headings added or

Submission - When you proposal is ready use the correct WebCT Drop Box and send it to the University. Do NOT send it directly to the tutor unless you have difficulty and there is no time to contact the University. If you send it to the Tutor the University system will not be able to detect a submission and your work will be marked as late and capped at 40% or rejected entirely. You may submit the work any time up to an including the due date. However, it is unwise to submit early as you may then find that subsequent learning makes you want to change what you have written.

Encouragement - You **MUST** expect to go backwards and forwards many times over all this work until you have a concise, coherent and lucid short Literature Review and full MSc Project Specification.

Study References - The Workbook and section references found in the sample Literature Review and sample project specification are to the Student Workbook Pack Release 3.2c.

Purpose - Once you have an approved or permitted project proposal based on part 2 you are allowed to construct a short Literature Review and a full MSc Project Specification which will be marked by the Research Methods tutor and reviewed by a University panel for final approval. If your specification is not approved by the University you will have another opportunity to try again in the next available cohort either with the same title or with a new one.

Part 3. Short Literature Review and Project Specification – Due date 16.3.2007 Value = Up to 85 Marks

There are 5 on-line tests and these will be made available for a short time periods every week for the 5 weeks starting in week 2. For each test in which you score 65% or better you will receive one mark. To do these tests YOU must find out where they are on the WebCT site and make sure you take note of when the tests are available. No exceptions will be made, if you miss any test for any reason you will NOT be able to take it at some other time.

Part 2. Online Tests – Taken at the WebCT published Dates Value = Up to 5 Marks

1. Title –
2. Problem Setting –
3. Presenting Problem Definition –
4. Real-World Target –
5. Research Question –
6. Intended Project Outcome –
7. Design for Collecting Primary Data –
8. Design for Processing Primary Data –

Declaration – I <student name> confirm that I have carefully studied all the Workbook references in constructing this proposal and that what is described here is a new work and is not copied from any source.

Project Proposal (Word Count =)

Here is a blank list of headings to help you formulate your project proposal.

There are no word counts for each heading but it is normal to find that item 7 and 8 are the most extensive as these show whether you have seriously thought about this as a research that is practical.

8. Design for Processing Primary Data – this is the second part of your design and its purpose is to generate the stated project outcome mentioned in item 6. Crucially here, you set out how you will process the structured collection of primary data in order to generate the stated project outcome. See the study project specification sample and associated notes which can be found in Workbook 3 sections 3.3.7 and 3.5.2.

7. Design for Collecting Primary Data – this is the first part of your design to generate the stated project outcome. This part of the design sets out your process for creating a collection of primary data. The core of this process is called a Basic Activity for Generating Data (BAGeD) and it must be stated here. See Workbook section 6.8, 6.9 and the study project specification sample and associated notes in workbook 3 sections 3.3.7 and 3.5.2.

Appendix A. Sample Project Proposal

This is a sample submission for guidance and you should NOT attempt to try to fit your idea onto it as if it were some sort of template in an attempt to reduce the work you have to do - if the tutor believes you are doing that your work will be rejected

The difficult elements are typically to be absolutely consistent and secondly to find an appropriate BAged. By consistency is meant that the whole submission links together and we don't find such things as the project outcome mentioned as X in one place and Y in another or the problem theme starts off as A in under one heading but migrates to B under another. If such inconsistencies are discovered, you will lose marks or be rejected outright.

Project Proposal (Word Count = 412)

Declaration – I Colleen McCullumb confirm that I have carefully studied all the Workbook references in constructing this proposal and that what is described here is a new work and is not copied from any source.

1. Title – Phishing – Preventative Measures

2. Problem Setting – email is a technology that almost everyone uses in the home, at work or on the move. Traditionally, email is a simple one-to-one or one to many message passing technology but it is now offered with enhancements that include voice, video, chat, file passing and file sharing where suppliers are attempting to present a compete communication environment.

3. Presenting Problem Definition - Phishing is identify theft using email where a personal message seeks confidential or private information from its recipient whilst posing as a legitimate request. The intention therefore is to fool the recipient of the message into releasing information which can subsequently be used for fraudulent purposes.

4. Real-World Target – Increase the awareness of computer users about the nefarious activity of Phishing and hence help prevent identify theft occurring and therefore reducing cases of fraud.

5. Research Question – How (interrogative) can Phishing (problem) be reduced or eliminated in order to control the risk of inadvertently releasing confidential or private information and hence incurring loss (target) by looking at typical phishing samples (spotlight) in order to generate some user guidance (suggestion).

6. Intended Project Outcome – my expected form of outcome will a set of guidance notes on effective strategies to use (including examples) in the event of a Phishing incident occurring.

7. Design for Collecting Primary Data – the BAged will be to identify phishing instances. My process will be to draw up a list of known phishing examples and use that to guide me in searching email logs for identifiable incidents.

8. Design for processing Primary Data – once I have the primary data in the form of a collection of phishing incidents I will pre-process that data by classifying them into general types and assessing the associated risk. In order to generate my intended outcome (see item 7) I will for each type on my list construct an illustration and an associated strategy to combat it contained in a set of guidance notes.

Appendix C. Personal Profile

This profile must be sent to the Research Methods lecturer (Mr Garlick) via WebCT in text only message of no more than 350 words (including headings). The University will use this information to guide you in project title submission and selection. The profile will be available to the University panel that approves your specification.

Profile (Word Count = ??)

1. Student No: This is issued by the University

2. Full Name:

3. Job Title: Your current job title (or state unemployed),

4. Company Name: where you currently work (or write none)

5. Company Profile: briefly state that major business of you company (or none)

6. Country: where you currently reside

7. Job Description: describe your core work (if unemployed say what work you would like to do)

8. Area of Expertise: list no more than 3 areas in which you regard yourself as expert

9. Strategic Business IT Project Area: what topic area or areas interest you relevant to MSc project selection

10. Formal Academic Qualifications: list in abbreviated form all your higher level certificated qualifications.

11. Other Qualifications: list in abbreviated form other qualification such as MCE

12. NCC SBIT PgD College Name: this must be the name of the College where you gained your NCC

Strategic Business IT PgD. Please make sure the name is correct.

13. Project Experience: briefly describe the last academic project you completed and any others that are of recent date.

14. Email Address: the one you expect to use for the duration of the course which must be the same as the forwarding address you set for your email in WebCT.

Example Profile (Word Count = 147)

1. Student No: 903210

2. Full Name: James Sheene-Southwood

3. Job Title: IT Project Manager

4. Company Name: BlueBird Systems Ltd

5. Company Profile: bespoke software system in ticketing systems

6. Country: England

7. Job Description: Managing Business Systems Applications Developments including Requirements Gathering, Business Analysis and System Design using Prince2 methodology mainly in the inventory

Management area.

8. Area of Expertise: Project Management practices but I also have some experience in Web based

development and technologies within an IBM AS/400 environment

9. Strategic Business IT Project Area: inventory management in the leisure industries particularly with

regard to entertainment machines.

10. Formal Academic Qualifications: BSc (Hon) Computing, PgD SBIT

11. Other Qualifications: none

12. NCC SBIT PgD College Name: Purpletrain.com UK

13. Project Experience: Last academic project was a Web based ticketing system for a laundry service.

Professionally my most recent work covered Technical Design of a web based invoice processing system

for a UK holiday company

14. Email Address: james.sheene@googlemail.com

Blank Profile Headings (Word Count = ??)

1. Student No:

2. Full Name:

3. Job Title:

4. Company Name:

5. Company Profile:

6. Country:

7. Job Description:

8. Area of Expertise:

9. Strategic Business IT Project Area:

10. Formal Academic Qualifications:

11. Other Qualifications:

12. NCC SBIT PgD College Name:

13. Project Experience:

14. Email Address:

Appendix D. Project Topic Ideas
Some ideas for final Projects and for use in this assessment – you don't have to select one of these they are just to give you a flavour of what you might look at. The list below was written as general ideas but they could always be applied to a particular situation as well.

No two students will be allowed to use exactly the same idea so it is important for you to get started before all the good ideas are selected and allocated.

Security	
1	Anti-forensic tools (eg Evidence Eliminator)
2	Anti-spyware – a business and personal necessity
3	Awareness Training on Internet Perils for Company Staff
4	Beware of online risks – enterprise users engage on riskier online behaviour than home users
5	Business Skills needs of IT Security Officers in Organisations
6	Comprehensive IT Vulnerability Management
7	Cyber spying
8	Data: Lost, stolen or strayed (off site backup storage for tapes etc)
9	Domain name crime
10	EPS (End Point security)
11	Forensic IT an Essential Business Resource
12	Forensic Tools (eg Windows Washer, Privacy Suite etc)
13	Hackers – Looking for fortune not fame
14	Illegal Downloads and business risk/costs/integrity...
15	IP based surveillance systems
16	IT Security Management and its Impact on Business success
17	Organisational benefits of security surveillance
18	Password Overload and Business Security
19	Protecting the desktop
20	Replacement of names and Passwords – What are the security and Usability implications
21	Secure ID Applications
22	Security – the users is his own worst enemy
23	Security in Kiosk installations
24	Security Software interfaces and personal freedoms
25	Security Violation Reporting – How Management Deals with This huge Volume of Data
26	Storage Security
27	The Ethical Hack – A framework for business Value penetration attacks
28	The Insider- Fighting the Enemy within
29	Usability and its trade off with security
30	Usage patterns in Kiosk installations

Project Management	
1	Analyse, plan, evaluate or report on an IT Project
2	Computing industry standards and their impact on business
3	Configuration Management Software in large scale IT installations
4	Define the role of ILS in a commercial sector IT procurement programmes
5	Desktop Lifecycle Management – A new MS Provision
6	Ensuring the IT projects Deliver Business Results
7	Explain the implications of ILS usage in IT installations
8	How important is user acceptance in the utility associated with IT systems
9	How IT can help with Life Cycle logistics in asset Management systems
10	IT and Logistics Management
11	IT Project Management Practice could be improved by the Use of Emotional Intelligence
12	Life Cycle logistics in IT systems
13	Managing IT system integration
14	Report on commercial applications of ILS techniques or philosophies
15	Software Portfolio Management – The Proving Model
16	Software risk management and its implication for IT strategies
17	The requirements gathering process is a major cause of project Management Failures
18	The role of prototyping and user involvement in requirement gathering and proving
19	The role of user training in Requirements gathering

8	Copy write protection for online trade marks
7	Who owns the Internet – A big Company Takeover
6	The role of Learned Societies (eg BCS) in ensuring professional Competence
5	The Role of Ethics in Systems Analysis
4	The effect of Ethical decision-making in the implementation of a Business Information System.
3	IT professionalism is essential for the full development of the industry
2	IT ethics and the economy/business
1	IT and its role in Social Inclusion
Ethics	

7	Storage Area Networks and their Impact on Business Policy
6	SAN and Continuous Data Protection
5	Modern Societies Dependence on Electronic Storage
4	Modern developments in integrated storage management
3	ILM (Information Life Cycle) – Controlling the Data Mountain
2	Entry level SAN and the SMB/SME
1	Data life cycle management
Storage and Data Manager	

21	Web Based operating system – Is there a future?
20	Ultra Wide Broadband – and its impact on business
19	The Paperless Society – an impossible dream?
18	The Effect of dual or triple core processors on worker productivity
17	Speech recognition system increases wider participation rates/increase worker productivity/ etc
16	Sourcing New Technology for enhancing business success
15	Software agent technology and its role in improving search engine performance by profiling usage.
14	Software Agent technology and its future role in mobile computing
13	Software Agent Technology and its use in improving web applications
12	Screen reading Software Efficacy as a solution to enable the visually impaired to use business software
11	RFID in Baggage Handling
10	RFID in a retailing Context
9	Portable PCs and their business future (ie blackDog)
8	PDA Revival – Is there a Business Future?
7	Optimising business functions by sourcing new information technology
6	Keyboards and their impact on system productivity
5	How new technologies related to location commerce might affect business policies
4	High Speed Broadband and User services
3	High Speed Broadband – its business impact
2	Digital Paper – A new Business Tool
1	Content Management systems and their place in a Modern Organization
Technology	

3	The role of IT training in ensuring personal productivity
2	IT training issues and the disabled workforce
1	Company policy on IT training affects user acceptance of IT system
IT Training	

8	The impact of IT on financial service provision has been significant.
7	The effect on Profitability of implementing an IT supported Asset management system
6	Small Business Accounting Software
5	Micro Payments a route to a cashless society
4	Making better IT Investment Decisions
3	IT hardware – A never ending Cost Centre
2	IT and Micro loans in Developing Countries (Grameen Bank and such things)
1	Electronic bill presentment and payment
IT in Finance	

Miscellaneous	
1	Community Technology Previews – A Marketing Strategy or a genuine attempt to communicate
2	Cyber Café – A world of Business
3	High Quality IT systems increases worker commitment
4	Reliance on private computer systems increases the costs of worker stress
5	The computer gadget market and its impact of Business IT
6	The Extended Enterprise (networks of suppliers, eProcurement etc)
7	The impact on worker productivity/morale of removing all personal systems
8	The IP enabled Economy

IT Services	
1	eAuction - The Future of Procurement?
2	Enterprise permeability and the supply chain
3	Impact of IT on international supply chain management
4	Improving Best practice in IT support units
5	Insuring IT based data assets and certification needs (BS 7799 ISMS)
6	IT Service Levels Agreement and Business Strategies
7	IT Service Management and Business Success
8	Outsourcing Document Management
9	Software Maintenance – A company wide strategy for business support
10	Vendor Service and Software Licensing

Exercise

Look at each of these simple supposed problem statements from students and say what faults are evident?

1. My problem is many customer complaints, loss of revenue and managerial weakness.

Fault - no good multiple problems so there is no clear focus and the student has simply done nothing here except offer the most superficial view. With some serious thought this could be corrected and the key problem theme might be about lost revenue for example.

2. My problem is lack of IT training.

Fault - no good because it is a solution since its resolution must be to provide IT training. Obviously, the student has decided what the solution is before doing any research and so in effect misses the problem definition out altogether. Here one if any though had been expended we might have found the problem is about accuracy in data entry, or customer helpdesk complaints.

3. My problem is to find a way to implement a network infrastructure

Fault - no good as this is an activity not a problem object and also it is of course a solution as one presumes that one wants to find a way to implement because of some underlying issue - this is a bit like saying my problem is to find a solution and no one would think that was a useful definition. One must start to ask why one needs to find a way to implement, what has driven you to the point where you realise that this is a solution - here it might have been a problem about user complaints, or excessive network down time.

4. My problem is growth of phone sales in Hong Kong

Fault - no good since this has nothing to do with strategic IT. It is also a bit odd to think of growth as a problem in itself as one presumes that one want growth.

5. The problem identified in the topic is how to solve the large number of customers' enquiries via internet broadband hotline service once the customers call the hotline centres.

Fault - here we are told the problem is how to solve the problem and we have to guess it's something to do with enquiries.

6. The project aims to identify key issues in this field, define areas of current and future research into the field, and prescribe solutions to dilemmas and issues arising, suggesting key areas of research and design, and suggestions as to the future. It will aim to call upon the experiences of those in the workplace, those who develop such interfaces, and the contact of those in academic research into the area, as well as existing studies.

Faults - here we are just given a long list of things to do in the project and clearly the student does not have the slightest idea what the problem is.

7. Organization face to strongest rivals at economy ages that product life cycle is changed extremely fast and lacks a hypothesis into IT infrastructure as handle rapidly changing business model. Finally, organization is inefficient and lacks a knowledge creative a new product and loss a market place.

Fault - here the English is so obscure that it is impossible to figure out what this student is talking about.

8. The problem theme is that the low accuracy of inventory records for existing inventory systems because of out-dated information. Example, querying those old PCs owned memory less than 32MB, the "old" system provided wrong information in such case.

Fault - here the problem is low accuracy although we just has to guess what exactly than means but the student also tells us that the reason is out-dated information. What this means is that there is no research for us to do here because we already know what the answer is and so such a project is worthless.

Exercise – look at these samples sent in by students and write some comments as if you were advising them how to improve.

Student Example 1

1. Title – Password Overload

2. Problem Setting – The organization I worked for has a lot of global business systems that are accessible via the public internet. This is a business need as employees are required to be mobile and to work based on flexible hours.

3. Presenting Problem Definition – Because these business systems are accessible over the internet, strong password policy must be enforced. Company policies require users to change their passwords every 90 days. Newer systems even require passwords to be at least 8 characters in length and must contain numbers, symbols and characters. Under these circumstances, users cannot remember their passwords thereby causing themselves to be lock-out from the system.

4. Real World Target – To reduce the number of lock-outs caused by genuine users. *Why?*

5. Research Question – How can the company develop a method to help genuine users in eliminating users' lock-outs?

6. Intended Project Outcome – The expected outcome will be to derive guidance notes on how to choose passwords that are secure and easy to remember.

7. Design for Collecting Primary Data – I will use BAged to find out the occurrences of lock-outs from the Helpdesk logs. This is achieved through the identification of instances where genuine users encounter difficulties in their passwords.

8. Design for Processing Primary Data – Once I have all the problems relating to password lock-outs, I will break them down by the different causes, confirming them they are caused by genuine users who have forgotten passwords. I will then develop the guidance notes, covering the recommendation of the countermeasures.

Student Example 2

1. Title – Sarbanes Oxley (SOX/SOA) Compliance – the IT automating strategies.

2. Problem Setting – H.R. 3763, also known as the Sarbanes-Oxley Act of 2002, was implemented in the wake of corporate reporting scandals, with the goal "To protect investors by improving the accuracy and reliability of corporate disclosures made pursuant to the securities laws, and for other purposes."

3. Presenting Problem Definition – The Sarbanes-Oxley (SOX) Act affects all public companies whose stock is traded on United States exchanges. SOX impacts public companies in many areas, including corporate responsibility and increased disclosure. Complying with these requirements often strains corporate budgets and demands increased time and energy to implement. Automating compliance with Sarbanes-Oxley regulations has become a critical component of most companies' overall compliance strategies. Since, the financial reporting processes of most organizations are driven by IT systems. Few companies manage their data manually and most companies rely on electronic management of data, documents, and key operational processes. Therefore, it is apparent that IT plays a vital role in internal control.

4. Real-World Target – Increase the effectiveness of implementing Sarbanes Oxley Compliance.

5. Research Question – How to implement Sarbanes Oxley Compliance with IT/IS automation in an effective way?

6. Intended Project Outcome – It is anticipated that this report will produce a clear implementation strategies in an effective way for Sarbanes Oxley Compliance. Some companies' example will be used for data processing and analysis.

This is the first of many examples I will use that are extracted from student work. Invariably there are faults and so I use these to try to show you what must be avoided in your own work.

Unfortunately, it is often true that the faults imply that the student involved has simply not studied with any kind of care the various reference and exercises I have given and so makes silly and obvious errors. However, you must be aware that this is an assessment and you only get one attempt so if you are careless, not really committed and do not prepare properly you will inevitably suffer as far as marks or concerned or if it is really bad you will be told to choose another topic and start again.

When you send in your work it is supposed to be the very best you can do so you have to be aware that it will go before a University panel and they will be only interested in your best work. My comments are show after every required entry, please read what the student wrote and what I have said by way of feedback and learn from that process.

Not accepted (0/10)

This is overall very poor work and has such gross errors in place that it is not worth really considering. Work of this standard is not in any way acceptable and in my view it was submitted without any preparation or thought and such outright laziness will not be tolerated.

1. Title - Sarbanes Oxley (SOX/SOA) Compliance - the IT automating strategies.

Tutor Comment - This is a very common topic area and so I will be looking for something a little new here. The title is quite good but it contains faulty English and the word "the" needs to be removed. However, I am interested in knowing why you used "the" and the implication of it is rather worrying to me as it implies that somewhere there are a set of strategies that anyone can just go and pick up and there are no others available or even possible - which of course cannot be correct so this indicates a lack of serious thought into what is being said here.

2. Problem Setting - H.R. 3763, also known as the Sarbanes-Oxley Act of 2002, was implemented in the wake of corporate reporting scandals, with the goal "To protect investors by improving the accuracy and reliability of corporate disclosures made pursuant to the securities laws, and for other purposes."

Tutor Comment - Here you have ignored what the heading is asking for and simply told us what Sarbanes-Oxley is and though what you say is mildly interesting it is NOT what was asked for. What we are looking for is the setting for the project itself. When required content is ignored like this, what can we conclude: the student cannot understand simple English, he has not bothered to study the references and the examples or he simply has no idea what to write so writes anything that sounds as if it might be right in some way - such actions are not acceptable and are indicative of poor understanding and attitude to setting out your research idea lucidly and robustly.

3. Presenting Problem Definition - The Sarbanes-Oxley (SOX) Act affects all public companies whose stock is traded on United States exchanges. SOX impacts public companies in many areas, including corporate responsibility and increased disclosure. Complying with these requirements often strains corporate budgets and demands increased time and energy to implement. Automating compliance with Sarbanes-Oxley regulations has become a critical component of most companies' overall compliance strategies. Since, the financial reporting processes of most organizations are driven by IT systems. Few companies manage their data manually and most companies rely on electronic management of data, documents, and key operational processes. Therefore, it is apparent that IT plays a vital role in internal control.

Tutor Comment - This is a very laboured as a definition and it is also unfocused, so here we see as possible candidates: corporate responsibility, disclosure, strain on budgets, resources, role of IT? What we have here is not a problem at all but a solution, automating compliance. In my opinion we have a student who has found a solution and is now trying to find a problem to hang it on. He is in fact not interested in the problem he just want to use his solution somewhere, anywhere.

unknown ones can we? Now on its own that would be such a trivial piece of work that it could not possibly be acceptable. He then suggests something called "future analysis" – this I cannot understand – does he mean he will get a particular product from a company that has used it, get their assessment of it or their pre-assessment of it. We simply do not know and frankly, I doubt this student knows either.

8. Design for Processing Primary Data - As long as I have the primary data, I will separate them into different types since they comply different code components of Sarbanes Oxley Compliance. To successfully create my intended outcome, I will construct illustration strategies and produce report on efficiency on different kind of products and their compatibility for the companies.

Tutor Comment – recall here that the intended outcome is implementation strategies. But all we know for sure is that we have a list of products so I cannot see, and we are not told how, we go from that simple list of products to these illustration (what does that mean) strategies as well as report on efficiencies and compatibility. This is just rubbish.

I. Title: Document Management Strategies

Show the problem set

II. Background: Documents are the lifeblood of an organization. Vital information for the organization is contained in these documents so their sound management is an important concern. Companies have their own storage and retrieval systems, although most are largely paper-based.

III. Presenting Problem Definition: Document management system (DMS) is the

computerized management of electronic and paper-based organizational documents. Despite of the inroads of information technology, traditional DMS still persists. Traditional filing systems have always been regressive and inefficient.

Craine (2005) also pointed to the fact that the DMS is not a panacea that would bring about a paperless office (Porter-Roth, 2006; Craine, 2005).

However, adopting an efficient and effective DMS does not come easy as resistance to it is also present. This includes investment considerations, security, and the flawed notion that DMS is the panacea that would bring about a paperless office (Porter-Roth, 2006; Craine, 2005).

III. Real World Target: Inform businesses of the merits of instituting an effective and efficient DMS manifested in reduced required time for data retrieval and store data and heighten security.

IV. Research Question: "What are the bottlenecks and areas for improvement in existing document management practices where strategies can be adopted towards a more efficient DMS?"

existing document management practices where strategies can be adopted towards a more efficient DMS?"

X

X

Deadline/Review with the Doc

V. Personal Theory: DMS is the integration of technology and management

systems custom-fitted to suit organizational needs. Researcher is convinced that DMS exhibits enormous potentials for an organization in the area of documentation handling and safekeeping.

VI. Intended Project Outcome: The intended project outcome is a discussion of

best industry approaches to DMS. The study will ascertain the variables or forces

that can spell the success or failure of an organization's DMS. Tried and tested procedures and best practices in DMS, from registration, distribution, filing, querying, retrieving, loaning, transfer and purging of documentation will be illustrated. The

appropriate transition from a conventional to a modern DMS shall also be tackled.

VII. Strategic IT Value: DMS is undoubtedly one of the most profound

technological breakthroughs that impact greatly on organizations. It spurs efficiency in document treatment and facilitates quick access to large amounts of information.

VIII. Design for Collecting Primary Data: Researcher would look into the

document life cycle to find areas where bottlenecks and complications arise, utilizing existing documents and interviews with key people in the organizations which will

serve as the primary data.

IX. Design for Processing Primary Data: A matrix that would match the

bottlenecks identified against best practices researched will be provided. A

Document Management Guide that any organization can readily use will be the

culmination and end goal of the study.

1. WORKBOOK 1. MASTER'S PROGRAMME OUTLINE

The Master's programme has two units of study: Research Methods and Project and the online programme notes together with this workbook pack cover all the information you need to complete it.

1.1 University Expectation

The University expects that when students submit work it is the very best they can do. In practice this will mean several things and all of them will be examined when work is assessed.

English – written English must be of a Master's standard and that means an IELTS score of at least 6.6 (or equivalent) is needed. If submitted written work is judged to be below this standard, students will NOT be allowed to progress to the project stage no matter what their actual language certification states.

Structure – work must be well structured and coherent. In practice students will most often work with a pre-defined set of headings and they must be used explicitly without deviation in their implied content.

Preparation – good work can only be produced if there has been adequate preparation. This will mean a thorough study of any and all references and exercises. Study does not mean a quick read through the notes or academic arrogance which says "I don't need it" or "I know all this stuff". This preparation also means working through the topic idea itself so that one becomes expert in a particular field.

Instructions and Guidance – all the work you submit will have to meet various standards in terms of layout and format and students are expected to following such guidance diligently.

Using other people work – all work submitted must be the student's own but within that work they may refer to the work of others but all material used must have proper attribution. Thus, if another author's work is copied, paraphrased or summarised it must be properly cited. Students need to understand that paraphrasing (putting things in your own words) and summarisation will amount to plagiarism if not properly attributed. This is a very serious matter and the rule with regard to copying is very simple. If 6 or more words are copied then the sources must be cited and if 10 or more words are copied without attribution then that is regarded as proof of plagiarism

Student's Own Work – the submitted work must be entirely constructed by the student and to do this it is necessary to weave into ones own ideas and thoughts the work of others. One may use the work of others to lend support to a proposition, or to include a definition or an explanation and so on. In other words it is not so much a question of how much of another person publication one uses but what one does with it in constructing ones own research work. In short scholarship is acknowledging and using the work of others whereas plagiarism is using the work of others and in so doing attempting to fool the reader into thinking it is ones own.

Respect – when writing one is doing it for another person to read and it's therefore a grave sin in those circumstances not to offer the very best one can produce.

Need - only quote, paraphrase or summarize when it is clearly adds to what one is saying and it is not just common knowledge or obvious. The key task is to formulate ones own ideas, in your own words by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

1.2 Overview of Unit Assessment

The two units: Research Methods and Project are assessed separately and students must in each one gain at least a pass grade in order to qualify for a Master's award. The assessment artefacts are.

Research Methods Unit (15 Credits)

The Research Methods Unit will be taught over approximately 12 weeks and assessment details will be published to you early in the Unit. The assessments are as follows.

Assessment 1a - development of a project specification plus a short literature review

Assessment 2 - a coursework on statistics.

Project Unit (45 Credits)

The Project is an extended research exercise where students will be guided by a personal supervisor. For students who have passed assessment 1a, approved projects will start a few weeks after the end of the Research Methods Unit and last for at least 18 weeks. There is only one assessment as follows:

Assessment 1b – prepare a full research based project document based on the specification developed in assessment 1a. The details of what is required in the Project itself can be found in Workbook 9.

1.3 Research Methods Unit Assessment Overview

This unit of study requires about 150 hours of effort from each student and will cover research principles, research ideas, research techniques as well as statistics. Assessment details and due dates will be made available early in the study period for the Unit in WebCT.

1.3.1 Assessment 1a – Preparation, Literature Review and Project Specification Development

The first unit event will be related to the development of a project specification and is in two stages.

Part 1 – Project Proposal Approval (up to 10 marks) – when the Research Methods unit begins students need to gain approval for a project title/idea. The university will supply a list of ideas or students may bring one of their own as long as the related project outcome has a strategic business IT dimension, it is new work, it involved learning in IT and it is a Master's level activity. In the approval process students have to write a short submission to a set format and send it in a plain email to the Research Methods tutor whose decision is final. This process must be completed by the due date set in the Assessment 1a papers (normally about week 6)

Students are permitted ONE attempt to gain marks in each cohort at this stage and one of three outcomes is possible:

Approved – the submission, whilst not necessarily being perfect, meets all the above project criteria and the outline is judged good enough for the student to begin work on the specification. About two weeks after approval is granted a supervisor will be allocated who may assist you in finalising the project Specification.

Permitted – the submission has a suitable idea but its construction is judged to be of poor quality but the student is given the benefit of the doubt and is expected to make good in the specification. No supervisor will be allocated and final approval will be depended on the quality of the final specification.

Rejected – the work is received after the due date or submission does not meet the criteria for a project in this degree and a new topic must be chosen and a new application made. Most often this is because there is no Strategic Business IT, the project research is regarded as trivial or plagiarism is detected.

Part 2 - Online Self Tests – these will be available at set times for a set duration every week for the first 5 weeks. Typically 1 mark will be awarded for each test in which you score 65% or better. Students should note that missing any test for whatever reason means the recorded score will be set to zero automatically as there is no provision for taking the test at another time or by another method.

Part 3 – Short Literature Review and Specification Approval – based on an approved or permitted project proposal students prepare a short literature review and full project specification which must be posted into a WebCT drop box on or before the assessment due date. The Research Methods tutor will review the work and write a feedback report for each student. The specification and feedback report will then be placed before a University panel who will decide whether it is appropriate for a Master's level project. At the end of the specification approval process one of four outcomes is possible:

Approved – students with an approved project proposal will have their named supervisor confirmed. Students with a permitted project proposal status will be allocated a supervisor. The supervisor will be automatically sent a copy of the feedback report and specification. Approval will not mean that a specification is perfect and it is expected that students will take note of any feedback given by the Research Methods tutor or the allocated supervisor to further refine it.

Approved Conditionally – students with an approved project proposal will have their named supervisor confirmed. Students with a permitted project proposal status will be allocated a supervisor. The supervisor will be automatically sent a copy of the feedback report. Conditional Approval means that there are some significant concerns that must be addressed before work begins and students are expected to redraft their specification, based on feedback given by the Research Methods and in discussions with the allocated supervisor.

New Topic – this means that a student specification has been rejected in its entirety and another topic must be chosen and work must begin again by seeking approval for the new topic before writing a new specification for submission in the next available cohort. This action is most often used when the University decides that the work is trivial, or the work has no significant IT content, or the student has submitted a specification without gaining approval for the topic, or plagiarism is identified.

Plagiarism is Identified – no approval is given and the relevant student work is subject to review by a disciplinary panel. Plagiarism is a form of deliberate deception in order to gain advantage and will always be treated with the utmost seriousness and may even result in students being dismissed from the course.

1.3.2 Assessment 2 - Statistics Coursework

This is usually a set of questions and mainly deals with quantitative data. The submission date will be published to you.

1.3.3 Calculation of Research Method Unit Mark

The overall mark for the Research Methods unit will be calculated as a weighted average for assessment 1a and 2 with the actual calculation being $0.7 \times \text{Assessment 1a percentage mark} + 0.3 \times \text{Assessment 2 percentage mark}$ in which a pass is indicated by scoring 40% or more overall.

1.4 Assessment 1b - Master's Project

This unit of study requires about 450 hours of effort, guided by a University appointed supervisor and based on the specification developed earlier in the programme. The actual project document must be supplied in the form shown in section 9 of these notes and is expected to be of about 15,000 words maximum (excluding appendices).

Once allocated a supervisor, students will be asked on what date they wish to submit their project. The only rule regarding project activity is that it must last at least 18 weeks and no more than 2 years but it will be a matter for students to negotiate with their supervisor and the University to agree a submission date. Students are allowed to make small changes to the specification during the project process but they must be approved by the supervisor and must not amount to a change of the topic that was approved.

2. WORKBOOK 2. RESEARCH METHODS CHAT AND STUDY PLANS

This is a general plan for study for this course. Chat sessions are important because they are collective and interactive and typically focus on just one important feature of research and to get the best out of the course students need to prepare properly. That means reading the notes, doing the multi-choice tests that go with each chapter, studying the Workbooks and contributing if you can to the discussion boards.

2.1 Contact Mechanism

Contact with students is through email, discussion boards or chat. Email is very important and you should ensure that you use an Internet based service so that you can get mail almost anywhere. It is good practice to create an email account just for the duration of the course and a common choice is GoogleMail because the storage space is, for all practical purposes, unlimited. If you are not able to create a GoogleMail account let me know and I will send an invitation to you. It is important that only ONE email account is used for communication and that address is made know to the Research Methods tutor as follows.

Whatever, mail system you use it is advisable to set mail forwarding from both your WebCt accounts to your personal one to ensure that you get mail as soon as it available. It is also useful if students have a Skype or IM account as many tutors allow direct access if they are online. Skype is preferred since chat, voice and video are all catered for and during contact one does not get bombarded with advertising. Internet email services vary considerable but my recommendation is that you only use a service that:

- Provides a virtually unlimited storage capacity
- Guaranteed to work from almost any location: hotels, Airport, etc
- Allows you to set a mail forwarding address (most services do not so check this with care)
- Provide quality SPAM filtering, virus checking and is not on the SPEWS blacklist
- Allows POP redirection (so you can use Outlook and send from databases etc)

2.2 List of Workbooks Sections Available

Here is a list of all the workbooks in this pack. Students must read them as the course progresses and tutors will expect a committed familiarity with what they say.

No	Workbook Name	Comments
01	Master's Course Outline	General overview of course and assessment structure
02	Research Methods Chat and Study Plans	Lesson plans for the chat sessions and student study plan
03	Project Specification Notes and Examples	Shows what a submission should look like with some helpful hints
04	Sample Literature Review and comments	Shows what a submission should look like with some helpful hints
05	Literature Reviewing	Guidance on constructing a review
06	Major Project Elements	Notes on writing a clear aim and a set of corresponding objectives
07	Basic Research Methods Checklist	A list of several possible research methods for quick reference
08	Bibliographic Referencing Harvard APA	Notes on how to use and cite source literature
09	Writing Up a Research Project	Sample content outlines on how to write your project document
10	Project Submission Form	A checklist to use before project submission
11	Marking Form Study Format	A copy of the form use to grade your project submission for reference
12	Marking Form Engineering Format	A copy of the form use to grade your project submission for reference
13	Project Mark Reconciliation Form	A copy of the form to reconcile marks when markers cannot agree
14	Supervisor/marker notes and grade criteria	Use by supervisors and markers to assess project work
15	Unit Level Feedback	Form that allows you to give feedback on each unit you study
16	Research Methods Master Notes	Complete course notes as a pdf file (not in this pack)
Table 1. List of Workbooks		

2.3 Complete Study Plan

Students must work in a committed way for the 12 weeks during the Research Methods unit and submit the work required on the set dates – there will be no extensions given other than for sickness or other indisposition (in which case students need to complete an ECF and provide documentary evidence of incapacity). Failure to deliver on time without permission will mean that the student unit result will be recorded as a fail. For the whole course the timings in hours are approximately as follows:

Course Element	Time	Comments
Chat Sessions	25	Including preparation and summarizing the chat log
Regular Visit to Site	25	For email and discussion board
Study Notes/Text Book	35	Including making notes and doing the tests
Preparing Submissions	65	Including reading the relevant workbooks and topic details
Table 2. Overall Research Methods Unit Study Plan		

2.4 Recommended Timings for Completing the Research Methods Work

Please look at the following list of times for preparation and carefully plan a way through this unit using these estimates.

Course Element	Time	Comments
Statistics Questions	20	There will usually be 4 questions for you to work through.
Literature Searching	10	The key to a successful submission of the assessments is that ones mind is fully prepared with all the knowledge needed.
Task Description	5	Here students prepare a project proposal: the research question, the form of answer expected, the Basic Activity for Generating Data, data specification and decision on a research method.
Project Idea Approval	5	The format used for this can be found in the Assessment 1a description
Research Plan	5	Here students prepare a plan for collecting primary data. This is not literature searching, it is new and original research
Short Literature Review and Project Specification	20	A partial short literature review and comment is provided in Workbook 4. The Project Specification format is presented in Workbook 3.
Table 3. Coursework Submission Plan		

2.5 Recommended Five Week Development Plan

In this course students must write a project proposal as soon as possible using the format set out in Assessment 1a. However, the basic project idea must be developed and refined carefully and typically it will be done in the sequence shown in table 4 where items in blue are specific to Engineering and items in red specific to study projects. Typically this refining process start is week 3 of the course

There is NO short cut in this work and the standards are very high. The expectation is that you will read and study the notes, examples and exercises with dedication and care. Failure to study with care is usually obvious in the quality of the work prepared, so work hard and think through carefully all the steps below – there is NO substitute for thinking your own idea through. There are plenty of examples to guide you but these examples are not templates they are there to help you gain understanding and not as some sort of quick fix to the work.

If the University sees in your work that all you have done is copy the example substituting a few words here and there then it is very likely your submission will be rejected. The University is looking for students who are thoughtful and careful in their work and through a process of hard work each student must demonstrate commitment high standards – nothing else is acceptable.

Week	Work Recommended
2	<p>Topic Area Research – this is about thoroughly understanding the topic area in which your problem is set. For example, if one was looking on Inventory Management using IT in a fast moving retail environment. that is where your literature research efforts are to be directed. So one would look at inventory management itself, warehouse based systems, shop shelf systems, POS systems, tracking fast moving but small value items, restocking, forecasting, re-ordering and so on. The idea is that you take time to think of all the aspects of the topic and then you try to become knowledgeable in them. There is no short cut here and the work must be done thoroughly and with commitment.</p>
3	<p>Presenting Problem Definition – every project will be based on a real-world problem of some kind. Student must define the problem as accurately as possible and that will be the theme of this first work element. Notice the intention is to have just ONE problem definition. (See Workbook 6 section 6.2 and 6.5)</p> <p>Target – this is the intention of solving the problem itself – that is what real-world benefits will result. For example, the problem might be about accuracy in inventory records and that would imply that if we can find a suitable project outcome that can be used to alleviate that situation then it will results in the target of for example reduced inventory costs. Problem and target are two side of the same idea. (See Workbook 6 sections 6.3)</p> <p>Research Question – here one tries to encapsulate the problem definition and ones theorising into a concise and lucid question that will form the focus of the research effort. (See Workbook 6 section 6.7 and 6.9).</p> <p>Theorizing based on the problem Theme – here one theorises about possible causes of the problem and corresponding solutions. In the case of inaccurate inventory records we might theorize solutions as being based on: production of a training plan for staff, feasibility report on possible use of technology, development of a sales policy and so on.</p> <p>Project Outcome Form – during theorization choose what might be regarded as a best solution and this becomes the single outcome intended for a project. For example, if we take the problem mentioned above of inaccurate inventory records then a project outcome could be a feasibility report on the use of RFID as this might be seen as a way of solving/partially solving the stated problem. (See Workbook 6 section 6.4 and 6.7)</p>
4	<p>Primary Data Definition Outline – the primary data definition is affected by means of the BAGD and it needs to be focused on the problem definition and the expected form of answer. (See Workbook 6 section 6.6, 6.8 and 6.9) In Engineering projects the outcome will be an application of some kind and that needs to be described.</p>
5	<p>Aim and Objectives – in the aim and objectives you sharply focus ones project by stating the means whereby one gets the major project outcome by a series of minor ones in order to achieve the project real world target. Of particular significance here is that the distinction between a project outcome and a project target is thoroughly understood. (See Workbook 6 section 6.11)</p>
6	<p>Research Design – this is the core of any project and it is the place where one expects to see serious and consistent thinking about how the presenting problem is to be resolved by collecting and processing primary data in order to generate the expected project outcome that will eventually lead to a real-world benefit called the project target. There are three elements as follows. (See Workbook 3 section 3.2, 3.3, 3.4 and either 3.5.1 or 3.5.2 as appropriate)</p> <p>1. Research Method Selection – this is an overarching framework used to guide and control the research effort. There are many Research Methods and it is necessary by a process of logic based on ones Research Question and it primary data needs to select and justify a suitable method. For Engineering projects the research method is focused on collecting application requirements. (See workbook 7)</p> <p>2. Design of Primary Data Collection Plan – based on the Basic Activity for Generating Data which focuses on the core data needed and then that basic activity surrounded by a process that allow reliable collection of the primary data. (See Workbook 3 section 3.5.2). For Engineering projects the plan is based on the outline application proposal which focuses on the core requirements and outlines a process or processes that allow reliable collection of the requirements. (See Workbook 3 section 3.5.1)</p> <p>3. Design Primary Data Processing Plan – with a collection of primary data in some suitable form one can apply some processing to it in order to arrive at the expected project outcome. Typically this might be statistics if the data is quantitative, various forms of text analysis or diagramming if it is qualitative. (See Workbook 3 section 3.5.1 or 3.5.2)</p> <p>For example, if one conducted a survey on the effects of SPAM on personal productivity then this might have been done with a questionnaire with say 20 questions. Now processing each question and drawing charts and graphs is NOT the same as explaining the effects of SPAM on productivity – to do that one must consider the whole survey where each question would be a dimension of the problem space. It follows that typically one pre-processes the data collection in some way and later using the results of that pre-processing we further process the data to get the intended outcome</p>
Table 4. Specification Elements Work Plan	

2.6 Critical Reflection

Students must expect to go back and forth over their work because as knowledge and understanding grows one will inevitably see that some of one's earlier work was incorrect or not as clear as it could be or maybe it can be improved in some way. This revision strategy is very important as a common fault with research work is that it often lacks consistency because there was no serious reflection on earlier work.

2.7 Chat Session Profiles

The following is a simple guide as to what students will be covering in the online chat sessions. These sessions are extremely important as they are usually interactive and are based on using examples. The research Methods Unit will involve a chat session roughly once every week – half these sessions will be based around the notion of research methods and half based on statistical processes.

2.7.1 Chat Session 1 – Setting up a Project?

This chat session will be a discussion of what is meant by research. The chat will focus on the idea of a presenting problem, target and outcome as the basic project building blocks. From this the chat will move to discuss a framework to surround a research project and a look at some of the core techniques that must be mastered. To prepare for this chat read Workbook 1 and 2 and Workbook 6 section 6.2 to 6.6.

2.7.2 Chat Session 2 – Refining a project Idea?

This chat will take the form of a discussion on how a project idea is explored and focused and a full example will be used followed by an open discussion and questions from students.

To prepare for this chat, students should be familiar with the title approval format shown in Assessment 1a and the specification examples and notes shown in Workbook 3 sections 3.5.1 and 3.5.2. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea. Of particular concern in this chat is the notion of presenting problem Workbook 6 section 6.2 and form of answer (project outcome) in Workbook 6 section 6.3 and 6.7, Basic Activity for Generating Data Workbook 6 sections 6.8 and 6.9. Students must work hard on these three ideas if they are to form an acceptable project specification.

2.7.3 Chat Session 3 – Research Method and Research Designs

In this session a research design will be developed based on a personally developed problem definition, research question, form of answer and Basic Activity for Generating Data. To prepare for this chat students should be familiar with the title approval format shown in assessment 1a and have studied the specification examples shown in Workbook 3 sections 3.5.1 and 3.5.2 as well as the associated notes in section 3.1. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea.

2.7.4 Chat Session 4 – Literature Reviewing and Working in a Scholarly Manner

In this session some examples of student work and how they write down their ideas will be examined based on scholarly principles. This will be followed by looking at a process that applies equally to what one writes and what one reads. The remainder of the chat will examine several excerpts from student work that exhibit common faults. To prepare for this chat read workbook 8 on citation styles and bibliography, chapter 4 of the notes and Workbook 5 and it might be useful to read through the sample short Literature Review in Workbook 4. In addition, it will be useful if one look at one's own way of using primary source materials and find some examples that are good and bad.

2.7.5 Chat Session 5 – Aim and Objectives

This chat will focus on how to write an aim and a set of objectives based around a problem definition and a Research Question. To prepare for this session read Workbook 6 sections 6.11 and Workbook 9 section 9.6.3 but also consider one's own project idea and what might be suitable in that case.

2.7.6 Chat Session 6 - Open

This chat will look back over the course and typically review faults that arose out of the assessment of the project specification. This will be supplemented by a discussion as to how various project elements: title, research question and Basic Activity for Generating Data, aim (not aims) and objectives are constructed but focused on the basic Activity for Generating Data.

2.7.7 Extra Chats - Open

Normally, each week there will be an open chat on Sunday at 1400-1500 where students may bring their questions, comments, concerns or grumbles. These are useful sessions but only when students come prepared with items that they need to discuss. These are not teaching sessions so the tutor will have nothing to say unless students come prepared with questions and are willing to participate.

3. WORKBOOK 3. PROJECT SPECIFICATION NOTES AND EXAMPLE

This section contains some guidance notes and sample completed project specifications - please consider them carefully. Do NOT copy them blindly – they are just for guidance and students must write their own in a way that matches what they want to do. The aim of the specification is to state a project plan as clearly as possible so one needs to be concise and precise.

3.1 Project Styles

In projects two styles are commonly found. There are some restrictions on these two forms depending on what programme you are on but the Tutor will advise on that issue. Briefly the two styles are as follows:

Engineering – here you design and build a software application, create a system design etc.

Study – here you design a research program to collect primary data in an attempt to find an answer to an interesting question. For example, one might investigate whether cascading styles sheets lead to simpler accessibility or you might evaluate the role of email management in business success.

3.2 Specification and Design

The following notes and samples for project specifications may help you prepare your own. However, it is important to think of it as being primarily a design for your project. The specification is essentially in three parts although it is not presented in exactly this sequence:

Preparation – this is not explicit in the specification but implies that you have thoroughly reviewed the literature at least to the depth of feeling confident that you know enough about the project topic to define and gather data. Implicitly, the University will look at your use of the literature and reference list to assesses how prepared you are for this work at this level and on this topic.

Background – this is about you setting the scene and defining a problem and then focusing on that problem with a Research Question, aim and a set of objectives.

Research Design – this is the culmination of the specification where you set down your detailed design for defining, collecting and processing primary data to get your stated form of outcome. It is very important to realise that this is a design and without a sound design things are likely to go very wrong.

In summary, one needs to think of the whole processes as starting with a problem definition and ending with a solution (your project outcome) and the element that connects these two things is your research design. It follows that unless you have a good design you will not be able to get from your problem to your outcome and that will mean your project fails.

3.3 Project Specification Headings and Formatting

All the following main headings and subheading must be used and students must not introduce others. As these guidance notes are read it is advisable to also look at the relevant examples in section 3.5 so that one can clearly understand what is being said.

3.3.1 Specification Header

Make sure all your details are entered correctly otherwise work may be misfiled or rejected because we cannot ascertain whose work it is.

3.3.2 Project Title Construction

Project titles must make clear sense in English and not be overlong. See Workbook 6 section 6.13.

3.3.3 Specification Intention

This element is to be a simple statement regarding whether there is an actual real world client for the outcome of this project or if it has some other purpose.

3.3.4 Project Task Description

The main function of this section is to explain what is going to be done using the suggested headings below and as shown in the sample. The headings are intended to be precise and if students ignore or change them or use them for any other purpose the work will be rejected. The actual selection of headings will depend on the type of project: Study or Engineering.

Engineering Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct an Engineering project task description and must expect to go over them many times before a concise and useful description is formulated. For Engineering projects please note that a functional description means that one says what the application will do for the users and not how it might be built or what architecture is involved.

Situation Overview – express here a concise and high level description of the existing or proposed application area.

Presenting Problem Definition – a concise definition of some real world problem related to data processing of some kind. This is an important step since unless one can clearly see what the problem is then any solution suggested may be deficient in some way. In most cases the problem definition in engineering projects is related to elements such as data availability, searching, access speed, storage, processing, accuracy, sharing, reporting, entry, updating, deletion, control, security, volumes, segregation, consistency, worker efficiency, process systematization, communication and so on. For the purposes of writing a specification the expectation is that students will focus their problem definition on one major aspect of the application scenario. See Workbook 6 section 6.2 and 6.6.

Real-World Target – a summary of the real world effects that are expected if this problem can be solved or partly solved.

Application Proposal – expressed as a concise description of the main system functionalities. When describing the main functionalities it should be done at a high level and it is recommended that they are all coherent and there should be no more than 10.

Ethical Overview – express here a concise review of any ethical impacts of gathering the primary data, processing it or system usage.

System Architecture – a concise description of the major or main architectural elements of the proposed application

Strategic Value – expressed as a concise argument that the application is able to deliver to the stated problem definition.

Study Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct a study project task description and must expect to go over them many times before a concise and useful description is formulated.

Project Topic Area Overview – a concise description of the topic area aspect being covered.

Situation Overview – a concise, high level description of the context in which the research is set.

Presenting Problem Definition – expressed as a concise statement of the single underlying problem leading to this study. This is an important step since unless one can clearly see and define what the problem is then any solution suggested may be deficient in some way. Study projects look at an aspect of strategic business IT and that might cover technology effectiveness, IT investment, user acceptability, development or improvement plans, feasibility studies, legacy systems and so on. See Workbook 6 section 6.2 and 6.6.

Real-World Target – what desirable real-world benefit is likely if the stated problem can be resolved or partially resolved. (See Workbook 6 section 6.3)

Research Question – expressed as a concise question that captures the problem definition and the real-world target. See Workbook 6 section 6.7 and 6.9.

Personal Theory – expressed as a concise and focused rationale regarding what an answer might be to the Research Question. See Workbook 6 section 6.5.

Intended Project Outcome – write a concise statement that expresses the expected major project outcome as it arises out of the stated problem definition and your personal theory and would be an answer to the Research Question. See Workbook 6 section 6.4, 6.7.4 and 6.9.

Strategic IT Value – here it is necessary to discuss ones intended project outcome and show that it is or leads to a Strategic Business IT impact that could eventually resolve the stated problem definition and hence generate a Strategic Business IT value. See example in Workbook 4.

Ethical Overview – a concise review of any ethical impacts of gathering the primary data, processing it, presentation or usage of results in the form stated

3.3.5 Overall Project Aim

This is a vital point in the specification because in a very concise manner a researcher brings together in one aim: the main project **activity** to get a stated project **outcome** as well as telling us what **data** is the focus of the activity and finally what the purpose or **target** for the project outcome is in relation to real-world problem resolution. It is essential that you fully understand these four elements as described in Workbook 6 section 6.11, 6.11.1 and Workbook 9 section 9.6.3.

3.3.6 Set of Project Objectives

To meet an overall aim it is necessary to achieve a number of milestones indicated by a set of objectives generating minor outcomes. Objectives can be hard to write and it is expected that there would be between 3 and 6 of them. See Workbook 6 section 6.11 and 6.10.2, Workbook 9 section 9.6.3.

3.3.7 Research Design

The Research Design is about the core elements that generates primary data and processes it into the form of answer expected (your project outcome). The Research Design is divided into two phases.

Design for Collecting Primary Data – a process or processes used to define and create a primary data collection. It has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the actual data and present that data.

Design for Processing Primary Data – a process or processes used to manipulate the collection of primary data to get the form of answer expected.

A useful analogy for a Research Design is that it is like deciding that you want a sponge cake and then working with a shopping list (a list of primary data that you want) to collect a bag of ingredients (collection of the listed primary data). Once we have our ingredients (primary data) we use a recipe to prepare and mix them (pre-processing the primary data) ready for the final processing step to bake the cake (like generating your form of answer). To reverse the analogy, if you were going to make a cake you would not walk into a shop and just pick up a random set of ingredients and then mix them all together into some muddle, bake it and expect a cake to emerge - no one but an idiot would do that would they?

The suggested headings to use are as follows and you are recommended to use them carefully in a step by step manner to construct a research design. You must expect to go over them many times before a concise and useful design is formulated. In the examples I have added the step numbers for clarity but you do not have to do that in your own work as long as all the elements are present.

Engineering Projects Research Design Format

Research Design Phase 1 – Requirements Collection Process

This phase is concerned with a process that generates a reliable collection of primary data which in an engineering project will be a set of requirements. See Workbook 7 section 7.10.

Define – here one bases the definition of requirements on the outline proposal document.

Location – state where or from whom the requirements can be found.

Collection Protocols – here it is necessary to select appropriate collection protocols such as: interview, observation, records searching and so on needed to collect the requirements under the standard four headings: Functional, Non-Functional/Performance, Technical and Usability. See Workbook 6 section 6.6.1.

Requirements Presentation – the requirements data once collected will typically be presented as interview transcripts, notes and copies of documents and lodged in the project document appendix as a kind of requirements catalogue.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulate it to get a design for the application. This is in two sections.

Overview – show how the various requirements are expressed in a design.

Specific – in any design there will be aspects that have no obvious means of expression and such aspects are typically written as a list.

Study Projects Research Design Format

Research Method – make a selection and write concise rationale for its use. See Workbook 7.

Research Design Phase 1 – Primary Data Collection process

This phase is only concerned with generating a reliable collection of primary data and is based on the Basic Activity for Generating Data but to be it has to be surrounded by a complete process.

Basic Activity for Generating Data – a concise description of the activity that forms the core of the primary data collection process. See Workbook 6 section 6.8 and 6.9

Primary Data – outline primary data items to be collected. See Workbook 6 section 6.6.

Location – a concise description of where the primary data may be found. In practice it may come from almost anywhere including extraction from existing secondary sources.

Collection Protocol – a concise description of the actual collection procedure which may be based on one or more of the following: interviews, questionnaires, observation, roles playing, document analysis and so on. See Workbook 6 section 6.6.1

Primary Data Presentation – expressed as a concise description of the way in which the primary data will be presented.

Research Design Phase 2 – Processing and Presentation

This phase is only concerned with a processing the collection of primary data in order to get the expected project outcome.

Design of Pre-Processing for Primary Data Collection – concise description of the processes applied to the raw primary data collection to generate a refined collection of primary data structured in a fashion that makes it suitable for generating the intended project outcome. (Workbook 6 section 6.6.3) (Please note that this step will not always be needed)

Design for Primary Data Presentation – presentation of data collection generated from the pre-process step - if that step is not needed just a presentation of the primary data.

Design for Generating the Intended project outcome – here the primary data collection (pre-processed if necessary) is used in some algorithmic or heuristic fashion to generate the intended project outcome.

3.3.8 Logistics and Tools

In this section the practicalities in terms of tools and time need to be considered. It is only necessary here to state things that are specific to this project, so it is not required to say things like: the library, Word, Excel, paper, pen, SPSS and so on as these are common and almost always available everywhere.

3.3.9 Outline Content List for your Project

This should be detailed enough to ensure that there is a clear idea of the final structure of the project document. Please be careful with the essential elements as indicated on the marking forms since if they are omitted a significant number of marks may be lost in the final project. See Workbook 9 table 6 and section 9.3.5 where typical chapter and section headings can be found. Workbook 11 or 12 (marking forms) need to be consulted so that no essential elements are omitted

3.3.10 References

This section is used to assess how well a student has prepared for the project activity. The University will want to see that the reading is current, comprehensive and focused on the topic area. It is expected that work in the specification will be supported from the literature particularly in the outline description and research method sections. Unless the literature is seen to be used in the various sections of a project specification it may not be approved although it is not expected that one cites from every book in a reference list. See Workbook 5 and Workbook 8 and make sure citations are in the Harvard APA style.

3.3.11 Project Plan

The plan must be developed by looking at ones contents list and considering what activities are necessary to generate the various project objects. Aim for around 12 to 20 activities lasting at least 18 weeks with any suitable start date. A project activity is something that is significant and requires planning and monitoring. So for example:

Prepare Metric Program – this is clearly a significant activity that has to be planned and monitored and so properly part of the plan

Select an Organization – this is an activity and might be important but it is doubtful if there really is a significant process involved here that has to be planned and monitored.

Outline Implementation Plan – this is not an activity so should not be in the plan.

The University will examine each plan and will want to see that it is focused on the project – the implication here is that it should be possible to see that a given plan supports a particular project idea not juts a copy of one of the samples or is so generic it might apply to any project.

3.4 Testing Your Research Design

A design must amount to a logical plan that takes a problem definition to a description to the expected outcome that will resolve the stated problem. The following are a useful check that a plan is sound.

Practicality – consider whether one has the resources to be able to carryout a plan. This is a very serious step and must not be taken lightly. It is all very well to have an elaborate plan on paper and to think because it all sounds logical that it can actually be done. In many cases a crucial test of practicality is to be sure that one can get the data from the locations specified.

Credibility – here one is expected to be honest and decide whether the plan will result in useful data and outcome. It is unfortunately true that many research projects end up being trivial because of poor identification of data and more importantly the choice of appropriate collection protocols. It is also worth considering the data processing functions as they must also be credible.

Confirmability – this test is about what would happened if the same research was done a second time with the same data – would the researcher end up with the same answer. To put it another way, is the processing method too dependant on an individual and that dependence may lead to bias.

Trustworthiness – here we are concerned that the conduct at all stages is such that one could have confidence that the results are genuine and not manufactured.

3.5 Example Specifications

Here are some sample specifications, they are complete except for the contents list and project plans but they are not meant to be copied without any conscious thought and any obvious attempt to do so will result in specification rejection.

3.5.1 Example Complete Engineering Project Specification

Here is an example engineering specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Detail - jan.smith@port.com for Cohort Started March 2006 (Word Count = 2,414)

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Intention – the customer is SIS and the application is expected to go live by June 12, 2006.

Project Title - An Assessment Marks Processing Application. (See Workbook 6 section 6.13).

Situation Overview

Currently, the core processing is done by staff members dealing with their own assessment marks, typically using Excel. The staff member then forwards his marks sheets, usually in paper form, to the administration office where the marks are collated using Excel to give an overall score for each student. These two marks sheets: individual unit marks and overall student marks are then presented to the Board of Examiners for scrutiny and acceptance. The process ends when a transcript is sent to each student detailing their results for that semester.

Presenting Problem Definition

The actors feel that the root problem is about consistency and accuracy given the sensitivity of the data but coupled with difficulties with storage, retrieval and reporting. (See Workbook 6 section 6.2 and 6.5)

Real-World Target – the desired effects here are that consistency and accuracy are both improved but at a reduced workload. (See Workbook 6 section 6.3)

Application Proposal

Based on the presenting problem there an application is needed that can offer us consistency and accuracy in the processing of assessment marks, both by unit and by overall student performance. The system to be called a mark processing system and it will have the following main functionalities.

Functional Requirements

1. Store name, address, year of study, name of course and unit details of all registered students.
2. Store the assessment patterns for each unit including weights and pass mark.
3. Allow for the entry, updating and deletion of any or all records.
4. Allow for the entry of assessment marks for individual entry or by batch updating via CSV
5. Report on marks for each unit including basic statistics.
6. Report of overall student performance, including basic statistics.
7. Produce student transcripts.
8. Provision for other ad hoc reports at a later date.
9. Secure access to individual results to be available to students through a portal.

Non-Functional and Performance Requirements

1. Store records for at least 6 years.
2. Allow for at least 6 simultaneous users
3. System must be capable of processing all the data and providing the reports within 10 working days. The estimated current volume is 145,000 data entries and 139 reports but this is expected to grow by about 7% per academic session.

Technical Requirements

1. Be developed in MS Access 2003.
2. For use under Windows XP.
3. All processing activities, including reporting, to be carried out using native Access facilities.
4. All processing is to be done using Access VB and no macros are to be used.

Usability

1. Be developed using normal windows formats and standard colours.
2. Fonts use in screen to be no smaller than 9 point and standardised at Ariel Narrow.
3. Assumed screen size to be 19".
4. Report to be printed as appropriate but with fonts never less than 10 point.
5. Data entry load per screen to be as recommended in DEF 981.90.
6. There should be some consideration of access via the portal for the visually impaired.

Ethical Overview

The collection of requirement here does not present any ethical problems. However, when in use the system contains personal and sensitive data and this aspect must be considered in the design

System Architecture

The intended application is essentially a database system with a web link. It will therefore have two interfaces: one a direct link to the database through the Access application and the other through a secure web interface routed through a portal but with only read access.

Strategic IT Value

The proposed application and its functionalities should address the presenting problem very well. In particular controlled data entry, data storage and reporting. This should reduce administration overheads and costs in a cost-effective manner.

Aim

To build an assessment marks processing system using standard MS products in order to ensure consistency and accuracy in the processing of student results. (See Workbook 6 section 6.11 and 6.11.1, Workbook 9 section 9.6.3)

Objectives (See Workbook 6 section 6.10 and 6.10.2 and Workbook 9 section 9.6.3)

1. To produce a detailed, departmentally based, marks processing requirements document.
2. To produce a detailed marks database design using standard documentation protocols.
3. To produce a detailed assessment functional design to include data entry, updating, deletion for marks processing and reporting.
4. To design the secure portal for student use.
5. To produce and evaluation report of the marks application.

Research Design Phase 1 – Requirements Collection Process

This part of the research design is concerned with constructing a reliable primary data collection for later processing into the form of answer expected. In this case the primary data collection is a set of detailed requirements for the marks processing application. The primary data that we need is related to the proposed major functionalities stated earlier and given to us in the form of a proposal. For each of the functionalities it is now necessary to decide. (See Workbook 7 section 7.10)

Location – The requirements can be found at various locations in Portsmouth. In particular

Detailed Functional Requirements: the appropriate targets for this exercise are: SIS office administrators, departmental course leaders, individual academic staff, Heads of Department and the University registry (for regulatory aspects). It may also be useful to make contact with a number of external examiners to ensure that the reporting arrangements are acceptable. In addition there will be various documents such as regulations and marks sheets

Non-Functional and Performance Requirements: the appropriate targets here are the Registry since they set examination and graduation dates as well as define the necessary reports. The office senior administrator also needs to be consulted for staffing and usage issue. During this process there must be detailed discussion with the department and the Registry over security issues as this is a major ethical issue. In addition there will be various documents such as regulations, external examiner reports.

Technical Requirements: the appropriate target here is the departmental technical to establish hardware and software profiles. It may also be necessary to discuss network and security issues with the University central computing department. It may be necessary to see network and PC specifications and various security profiles.

Usability Requirements: the basic design is based in Windows protocols so there are no particular requirements to be gathered. However, because it is possible to implement interfaces in a few ways particular usability requirements will be ascertained by use of a mock-up used with the administration staff. With regard to the Portal there will need to be discussion with the University webmaster over formats and protocols to be used. In addition there will be various documents defining standards and formats.

Collection Protocols – The collection is essential a survey format where each requirement aspect will be discovered by just three formats: (See Workbook 6 section 6.6.1)

Detailed Functional Requirements: expressed as interviews, document analysis (marks sheets and regulations) and some observations. It may also be necessary to use observation to examine any existing Portals.

Non-Functional and Performance Requirements: interviews, document analysis (marks sheets and regulations) and observations.

Technical Requirements: interviews and document analysis (system specifications and profiles)

Usability Requirements: interviews and document analysis (system specifications and profiles). In addition it will be necessary to run some focus groups to look at various interface design option by means of mock-ups.

Requirements Presentation – the requirements data once collected will be presented as interview transcripts, notes and copies of documents. These artefacts will be reviewed and a tabular format used to present the requirements and lodged in the project document appendix.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulates it to get a design for the application. This is in two sections.

Overview – here the vehicle used to present the various requirements in a design format will be UML. The mechanism will be to take the written requirements documents and map them to a suitable diagrams in the form of use cases, class diagrams and where appropriate collaboration or sequence diagrams.

Specific - where necessary a written list will be provided. These will mainly be used to state unambiguously the various non function, technical and usability details.

Logistics and Tools – Required Resources

All the hardware and software are available at the Client's premises and all work including requirement gathering will take place there. The major products needed are: Dream weaver and MS Access and scripting will be done using ASP.

Outline Content List for your Project

See project guidance notes for samples and they can be found in Workbook 9 section 9.3.5 and table 6 but you must also be aware of the marking forms that can be found as Workbooks 11 or 12.

Project Plan

Any clear format may be use but a typical format (but not events) can be found at the end of the Study Project sample specification.

3.5.2 Example Complete Study Project Specification

Here is an example engineering specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Literature Review & Project Specification (Study) – Jan Smith 341387 MSc Computing

Detail - jan.smith@port.com for Cohort Started March 2006 (Word Count = 2653)

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Intention – no customer involved and project results will be used to produce a research paper.

Project Title - Quality Control in Program Development - A Possible Strategy (Workbook 6 section 6.13).

Project Topic Area Overview

There is much interest in Software Quality assurance at present and this is for obvious reasons. Software applications are unlike normal products which wear out and can be tested over time to see where most wear takes place and hence calculate a mean time between failures. By this means failure can be effectively prevented by maintenance. However, in software such wear does not occur although an analogue of this is when other hardware and software components around the software, or the application itself changes and hence problems arise. Typically, we test program code and the more we test the code the more certain we become that it is robust.

Situation Overview

The research is set in The University of Portsmouth with the School of Information Systems. In that context it will focus on the programs produced by first year computing undergraduate students.

Presenting Problem Definition

The problem for developers is focused on knowing when code is robust and ready for release. (See Workbook 6 section 6.2 and 6.5).

Real-World Target

The benefit that would accrue in the real-world if this problem can be resolved or partially resolved is that developers can feel more confident about their product and therefore not risk costly development overruns and compensation claims from clients. (See Workbook 6 section 6.3)

Research Question

How can developers feel sure that software applications are ready for release in order to prevent costly overruns and client disappointment? (See Workbook 6 section 6.7 and 6.9)

Personal Theory

The topic is fraught with difficulty because there is no accepted way to measure program code to see how good it is or even to see if it is correct. Blithe (2002) explains that it is well understood that it is not normally possible to measure, using an interval and ratio scale, in any meaningful way the quality of program code. However, it might be possible to find some means of 'indicating' the quality of the code in the sense that one might be able to pick outliers by taking certain kinds of measurement. It is therefore suggested, that simple measurements of various code properties might be used to pinpoint outliers and hence shorten the testing cycle by transforming the measurement statistically into a pseudo Interval and Ratio scale form which is called Planar Similarity. (See Workbook 6 section 6.5).

Intended Project Outcome

It is expected that the form of the answer arising out of this theory will be a demonstration in the form of a report with graphical evidence that endorses the proposition that Planar Similarity is an appropriate software quality indicator in that outliers can be detected hence assuring the measurement process. (See Workbook 6 section 6.4 and 6.9)

Strategic IT Value

If Planar Similarity is indeed a useful measure of software quality it can be used routinely to examine software in production and give an early indication of quality and that will lead to shorter test cycles and hopefully more reliable software installations and a consequent reduction in cost. In fact Clitheroe (2003,p6) has suggested that detecting all code faults at the initial coding stage might save as much as 23% of development costs. (See example in Workbook 4)

Ethical Overview

There are no current users of the process being developed there would not seem to be any ethical consideration of importance. However, it is necessary to explain to the students supplying the sample programs the purpose of this study and assure them that none of this information will be used for assessment and allow them access to the results if they so wish.

Aim

To report on the efficacy of the Planar Similarity measure using simple metrics as a means of finding outliers in program code and hence reduce coding errors leading to development cost reduction and client approval. (See Workbook 6 section 6.11, 6.11.1 and Workbook 9 section 9.6.3)

Objectives (see Workbook 6 section 6.11 and 6.11.2)

1. To model the software construction process.
2. To report on appropriate simple and synthetic metrics that might be used as indicators of quality in application programming code.
3. To define a process that will extract the defined metrics for any piece of code.
4. To document a suitable statistical process for reducing the metric value set to just two dimensions.
5. To analyse and report on the data, including outliers, and hence derive some general conclusions regarding the utility of the Planar Similarity metric.

Research Design - Research Method

The chosen method will be case studies since I want to see the impact of the measurement process within a defined context and of particular interest in that context is student programmers with differing abilities in writing business application style programs. The case criteria are simple and amount to selecting a sample of students at a set point in their first year of study and a set of matched programming tasks. (See Workbook 7)

Research Design - Phase 1: Primary Data Collection Process

This part of the research design is solely concerned with constructing a reliable primary data collection for later processing into the form of answer expected.

Basic Activity for Generating Data

The basic idea is to compare a new piece of code with an existing piece that is known to be sound and take a series of measurement on each one that might highlight any differences and so indicate an outlier. The idea has some support based on early studies carried out by Sheene (1999) who noted that a reasonable means of indicating quality in program code is to compare similar pieces of code by calculating several metrics for each piece although he did not define how this might be done practically. (See Workbook 6 section 6.8, and 6.9)

Primary Data

This study will define 20 software metrics which will be calculated automatically and for each sample programme. The metrics that form the primary data collection for this research will be such things as: function density, function count, cyclomatic complexity, data associations, decision count, decision density, number of variables, number of function calls, etc. (see Workbook 6 section 6.6)

To set up the case studies three computer program specifications will be drafted with the students working in 'C++'. The specifications will be written so that the defined software application is, in each case, of a different style and progressively more difficult. An expert in 'C++' will produce a set of generics to match the requested programmes – it should be noted that a generic is an outline or skeleton of certain kinds or classes of program.

Location – The sample frame is all first year students on computing courses at Portsmouth University. This is around 350 students and my calculated sample size is 200 students, however, since the data collection process is automatic all 350 students will be used in this study.

Collection Protocols – The collection is essentially a survey format where the students will be given the relevant generics and the specifications and asked to write three computer programs of increasing complexity, one in each of three semesters. In this case there is a large data set to be collected and it is not practical to do the collection by hand. In view of this an application will be written that will process each student program so that metrics may be calculated automatically and stored in a suitable electronic file. Students will be requested to deposit their programs on set dates into an online drop box for both marking (not part of this study) and metric calculation. (See Workbook 6 section 6.6.1)

Primary Data Collection Presentation

The sets of primary data will be available in the project document appendix and will be presented in tables where the rows represent the sample programs (one row for each sample) and the 20 columns the metric values.

Research Design - Phase 2: Processing and Presentation

This part of the research plan will take the whole collection of primary data and manipulates it to get the expected outcome form, which was a demonstration that outliers can be detected hence assuring the measurement process. The processing is in three steps: manipulate the raw primary data, presented the processed data in graphical form and extract from the graphs features by manual inspection.

Design of Pre-Processing for Primary Data Collection (Workbook 6 section 6.6.3)

The metric data sets will be read directly from the files produced in phase 1 and then statistically processed to define a similarity measure for each program using principal component analysis and multidimensional scaling. The outcome of this processing will be pairs of values, one pair for each sample program, suitable for plotting in two dimensions.

Design for Results Presentation

The pair of values from the first processing round will be plotted in two dimensions, together with the results for the generics producing three graphs one for each program specification.

Design for Generating the Intended Project Outcome

Once the graphs are available it is then a simple matter to look for outliers in particular and attempt to explain their distance and orientation from the generic and other programs in the class. The contention is that similar programs will cluster together and ones that are different (even though the specification was the same) will show up as outliers and can be identified and examined to see why that difference occurred. It is hoped that the results will be similar for all three program in that data set and hence demonstrate that complexity is independent from planar similarity.

The final step is to use the identified outliers to go back to the actual program code to explain why the code produced the outlier. In this way it will be possible to get an indication of why a given program is deficient. This final processing step allows me to generate my report on Planar Similarity that contains my overall findings and evidence on its utility.

Logistics and Tools – Resources Required

All the hardware and software are available at the University. Since the data collection process is automatic the use of staff resources is minimal.

Outline Content List for your Project

See project guidance notes in Workbook 9 section 9.3.5 table 6 but you must also be aware of the marking forms that can be found as Workbooks 11 or 12.

4. WORKBOOK 4 – LITERATURE REVIEW & STRATEGIC IT VALUE NOTES/EXAMPLES

This is a sample of what is expected in assessment 1a, however, it only shows two elements: the strategic business IT statement and the short Literature Review. Try to keep in mind that this is just ONE example and do not try to copy it blindly or try to fit it into what you want to do.

Strategic IT Value

This work was based on trying to resolve or partly resolve the problem of low quality code leading to the need for costly re-work at later stages in the development cycle. The importance strategically of this work is that the outcome: a definition of new software metric will imply that it is possible to identify poor application code and this can be done at an early stage in the software development life cycle. The importance of this is that corrective action can be taken early in the development cycle and as a consequence costly re-work late in the cycle can be avoided or reduced. A secondary or added value element is that the results will allow the identification of good programming standards and this in itself will also lead to improvement and strategic advantage on all products delivered.

Tutor Comment

The key element here is that one relates the expected outcome or form of answer to its use in resolving the problem theme that was the basis of the project, and hence demonstrate a strategic business IT value. Failure to create a clear argument based on the problem theme and outcome leading to a strategic business IT value will mean loss of marks.

Literature Review (See Workbook 5 but note section 5.6 in particular)

Hiskett in his 1987 seminal paper on metrics defined several apparently useful metrics, the best known of which are 'program vocabulary' and 'program length' which are essentially metrics that count operators and operands and their usage in a given piece of code. Hiskett's metrics are easy to calculate but he was unable to show any strong correlation between his measures and program quality as defined by experts in the field. Similarly, Rogers and Hamerstein tried to use Hiskett's metrics as predictors of MTBF in accounting software but the results were inconclusive and no link could be found between the metrics and the type of software (functionality), accounting in this case, and the metric used.

Garlick, Sheene and Southwood (1999, p450) attempted a new approach that involved the notion of similarity, which they called planar similarity – that is two programs could be defined as similar because: they are written in the same language or they perform similar functions or they were written to the same standards or they are written to the same specification or they were written by the same team or finally they perform the same function. Their work is aptly summed up in the opening paragraph of their paper:

"The nature of any true measurement is easy repeatability and this implies that the style of measurements form a suitable metric space. This means that we need to define the nature of the similarity before we define a measure. In principle this is simple since it is easy to name the similarities but in practice it has been difficult to articulate a precise definition."

The similarities described above deserve further explanation but here only two of them in combination are used: similar language and similar or same specification. Similar language is easy to understand but at first glance it would seem that if two different programs are written to the same specification they are bound to be the same. However, after a little thought, it is obvious that if two different people write two different programs to the same specification the programs are certain to be different in many respects. It follows that the basic, though loose, hypothesis is that if planar similarity can detect a similarity (alternatively difference) in these programs - written to the same specification but by different people - it might be possible to use planar similarity to detect differences between two or more programs against any defined mode of similarity. Conversely, if it cannot be shown that a similarity exists between two or more programs written to the same specification then there is no hope whatever of showing any other kind of similarity with this metric.

Two final points need to be considered: what exactly is meant by software quality and why would a similarity measure be a good indicator of quality? To answer the first question we have only to refer to Kitchenham's 1998 paper where she defined five kinds of quality, briefly:

Transcendent View – quality is a kind of innate excellence, something felt rather than seen.

Product Based View - quality is related to the content/attributes of the product.

User View – quality is seen as equivalent to fitness for purpose.

Manufacturing Based View - quality is equated with conformance to specifications.

Value Based View - provide product at an acceptable price and conformance to a specification.

In this study the transcendent view was the one chosen as the basis of the definition of quality. The meaning of this view is defined by experts in the field – that is, can an expert in, say, Java programming make a judgement as to whether a given piece of code is good or bad – well, here it is argued that such an expert can and does such tasks routinely. Curiously there is very little literature on this idea of expert opinion within the software community but Gavin as early as 1978 touched on the subject. However, it is a reasonable conjecture and it will be used in this study – interestingly, if it can be shown that planar similarity can detect similarity (or equivalently differences) then it would also support the conjecture that experts can judge software quality.

Finally, the study will rely on the ability of experts to judge quality in software. This judgement is exemplified in the production of exemplar or generic programs. Garlick (2003, p98) has written extensively on this subject and the work is well known and will not be fully reviewed here. However, it is possible to define classes of program modules - validation, input, calculation, reporting and so on – it follows, that using the idea of similarity it is useful to create a standard or *generic* program or module for each class. Such a program can then act as a base line for all planar distances related to its application class and hence be a measure of similarity (or difference).

Using Garlick's idea we can let experts define our generic and then use that to compare with other programs – if we declare a difference then in simple terms we need to look at that program because it might be of poor quality and conversely if we declare no difference then we can fairly conclude that the program is sound.

Tutor Comment

The literature review is supposed to be a student's own work. As such it is a discourse that outlines the major areas of a topic area but amounts to an essay which is the student's alone. In practice this means that students must read deeply into the subject and then weave what is read into what the student already knows or believes in order to create a useful summary of the topic that will form a strong base for carrying out the actual primary data research - this implies that you 'master' the subject area and become expert in it.

It follows from the above that if all you do is copy or paraphrase from various sources without any significant comment or analysis on your part then it amounts to plagiarism and is worthless.

One final point is that when you write up your review in your final project document you should use various sub-headings and other formatting elements to structure the section to make it readable and meaningful.

5. WORKBOOK 5. LITERATURE REVIEW

The main function of this review is to ensure that one's mind is prepared with all the specific problem area knowledge that it needs to carry out the project and its primary research. In practice this implies the rather difficult task of integrating different ideas, theories and experiences into a thematic, informative, complete and clear discourse on your chosen subject area.

Preparation of the mind is done through adding your critical evaluative comment on what you find in the available literature and such critical reviews are typically hard work and not about downloading a few articles from the internet. The key characteristic of the greatest thinkers in history was absolute and unswerving honesty in all their thinking and that principle has never changed. They used their intellect and reasoning abilities to the full. They were honest no matter what the subject be it religious, political, business or academic. These men would not accept dogma from religion, politics or academic sources without subjecting it to serious critical questioning and of course this often meant great suffering for them.

5.1 Plagiarism

The KEY is honesty – without that your work is worthless – you may be able to fool some people but as Shakespeare said “This above all: to thine own self be true, and it must follow, as the night the day, Thou canst not then be false to any man. So when you plagiarize I may not know, the University may not know but YOU will always know that you obtained something falsely.

Plagiarism means passing off other people's ideas as your own. In academic life, it is one of the worst things that anyone can be accused of, as it is a form of stealing or cheating. It is fully expected that students will carry out research prior to completing a piece of work. This may include the use of books, journal articles, reports, manuals, notes and so on as source material. The material may be public, restricted to a closed set of people or with a security classification), or privately communicated. The principles are the same whether the material is on paper or in an electronic format. When you refer to an idea in a piece of your own work, it falls into one of several categories:

Common knowledge - many people know it and the information does not belong to anyone person but it cannot normally be deduced by you it has to be learned. It is probably talked about in several sources: the world is round, computers contain both processors and memory, OO is routinely used in software construction and so on. If you are sure that it is common knowledge, you do not need to cite a source. Be careful, authors will often write down in their own work things that are common knowledge so quoting them in that instance amounts to saying that a bit of what is common knowledge actually belongs to that author and that of course is an absurdity.

Obvious – many people know it and the information does not belong to anyone person but it can be deduced. It is probably talked about in several sources: companies tend to grow as time goes on, when the sun goes down it gets dark and so on. If you are sure that it is obvious you do not need to cite a source. Be careful, authors will often write down the obvious in their own work so quoting them in that instance amounts to saying that what is obvious to every one actually belongs to that author and that of course is an absurdity.

Published – this refers to an idea that found in a specific source or sources which is not common knowledge nor obvious but is nevertheless useful – in these cases you must always cite the source or sources of such an idea.

Original – you may include freely original ideas of your own. However, be aware that if the reader sees an idea that is not cited and is not common knowledge nor obvious, then they are entitled to believe that either it is a new idea published by you or you have plagiarised it.

5.1.1 Identifying Plagiarism

Plagiarism does not occur only when you copy words verbatim. Plagiarism is about ideas, and even if you express the idea in your own words, you may still be guilty of it if you do not credit the source. However, expressing an idea in your own words might often be good scholarship. The difficulty is that anyone can copy and paste a phrase, sentence or paragraph and cite its source. This is technically not plagiarism, but it's often very poor scholarship since it is obvious that such an activity tells us nothing about the learning, if any that has occurred

Scholarship is about showing your understanding and criticism of ideas. Simply copying, paraphrasing or summarising can only show understanding only to a limited extent. You need to "add value", that is make your own contribution to knowledge, to what you've read and you can usually only do this by expressing an published ideas in your own words and mingling them with your own thoughts and ideas.

5.1.2 Common Critical Devices

The essence then is to infuse your work with your own thoughts and ideas and let these mingle with what it is you have found in the literature. The most common forms of this are:

Interpretation - explaining and expanding on what you have found.

Criticism – discussing in order to judge whether the ideas are good or bad.

Decomposition or Analysis – to tease out the constituent parts of an idea.

Synthesis – by means of discussion and explanation link separate ideas together.

Selectivity - showing which ideas to include and which to discard.

Abstraction - taking an overview or defining a model or framework, usually by looking at examples.

5.1.3 Common Literature Tools

The following are the most common means of incorporating, in a scholarly fashion, the work of others into your own written work (a fuller discussion of these tools may be found in the notes).

Copy – use the exact words using quotation marks. A good rule is that each quote holds a single main idea, which you want to use and then you must introduce it and then follow it up with discussion.

Paraphrase – expressing something that you have found in the literature in your own words - the intention being to simplify, explain, or interpret a complicated idea. But take care there is a very fine line between simplifying, explaining and translating something and just being lazy.

Summarise – producing a précis or abridgment of a part of the source we have found. Essentially one is trying to capture the main points in an argument.

Analyse – the purpose here is to offer a detailed examination of some whole by scrutiny of its parts.

Synthesise – here the idea is to take parts and put them together into a new whole for some purpose.

You might find it useful to remember: copy in order to discuss, paraphrase to simplify, explain or interpret, summarise to capture the main points, analyse to understand and synthesise to build something new.

5.1.4 University Review Assessment

When the University looks at your Literature Review it will be trying to decide if you are committed and prepared for the topic and working at Master's level. If your work is poor in terms of structure, content and form you will find yourself failing. This is NOT necessary so long as you put in the work and ensure you understand how to use citations and the literature. I want to encourage you to do good work - it will ensure that you pass well and it makes your work a pleasure for the Examiners to read.

5.2 Review Content

The review is about your topic area and about you becoming sufficiently expert in it to deal with the problem that you will have uncovered. The intention is for you to offer a discourse that is focused, relevant, authored, measured, evaluative and expressed as a dialogue. (Notice the acronym FRAMED)

Focused – this means that your whole effort is focused on the topic area and the particular aspect of it that you are pursuing. So do not be tempted to add in other things just because they might be useful, interesting, and novel or you just have nothing else to say.

Relevant – any topic area aspect will itself normally represent a large body of knowledge and so one needs to continually ask if a particular element in the knowledge domain is relevant to your particular study.

Authored - any literature review is to be written by its author. This sounds obvious but it is all too easy to fill up a review with cited quotations, paraphrases, summaries and so on so that the 'hand' of the review author is not evident anywhere in the work. When this happens it is not an evaluative review at all but simple plagiarism. The author's 'hand' must guide and direct the review in an evaluative fashion so that the review is a message from the review author and not a recitation of what has been found elsewhere.

Typically this is done by using ones own skills and knowledge to introduce, comment, add to, modify and extrapolate from various primary sources available.

Measured – this is a matter of selecting and using the focused and relevant materials that you have found. Unfortunately, It is all too easy to pack in information in excruciatingly precise detail and so end up with a laboured entry that treats your readers as if they where completely ignorant of the subject area. So here one needs to just say honestly “is the entry a measured response to my and my readers, information needs”.

Evaluatory – authors sifts through the primary sources looking for materials to use. The essence of this sifting is an evaluatory outlook based on an awareness of your problem theme and your topic area. Care is needed because this process is not about searching for materials that you agree with or like in some way. Instead it is a contextualised response (what do you already know) and that may mean you find materials that are new to you, materials that make you change your own knowledge base and often materials that completely replaces what you thought was solid.

Dialogue – a review is a form of argument because good ones are based on a strong theme and in them one is trying to explain to, and convince your readers about something and so it is best if you think of it as a kind of dialogue in which you vicariously challenge them about your review theme and content.

5.3 What goes into a Literature Review

It will depend to a large extent what it is you are working on and what you want to say but the following list give some common ideas of content.

Challenge – this is two way: what you read challenges you and you challenge what you read for validity and applicability and so one might find new ideas or change our perspective.

Consolidation – reading widely consolidates your own knowledge base in that is can confirm or show any gaps in your knowledge.

Exploration - implies searching for new ideas, theories, concepts, rules and so on.

Self Check - affirm what we know for currency and accuracy

Support - the reading might support or be in opposition of ones views

5.4 Integrity and Evidence

This heading sums up research - integrity because it must be your own work and evidence because you MUST be able to show that your results have value. There are basically 4 strands to good work as follows

Dogma – this simply means things you have to take at face value. Most often they are things that are not open to reason in the sense that one is not allowed to question them and in some countries you can find yourself in serious trouble if you do. The problem with dogma is that by definition there is no logical support for it. Just to use a simple example, some faiths require you to have a beard or not eat pork as a matter of dogma – in such cases we usually cannot logically deduce that this is a right or wrong thing. It may of course be simpler than that since we all invent our own dogmas from time to time – for example it may be very simple such as ‘I will never buy a Ford car’.

We all accept dogma but that really is not the issue – the issue is that we should not accept it without some critical thought. There is at least one rational way of exercising critical thought on dogmatic issues and that is asking is the outcome of actions based on it good, bad, neutral or at least does not harm anyone. The trouble however, is that dogma sticks to us like super-glue and we will often go to great lengths to defend it and almost always this is done by sophistry (worthless arguments) and of course the notion of what is good or bad is not easy to define.

Reason – this is the ability to be logical and reason about what it is you are reading or writing. That is you are encouraged to ask questions and seek for a deeper understanding. This may imply that you accept new information, modify what you already know or reject something as no longer valuable.

Honesty – here we are talking about not taking things at face value and being honest with yourself about what you are reading or writing and asking does it all make sense and is it coherent with what I already know.

Motive – this aspect is about your reasons for wanting to read or write something. Now such motives can be high minded or they may be base. One must therefore always guard against tendentiousness (the author simply wants to convince a reader of something and may use any means to do it) in ones own writing and be watchful for it in the writing of other.

5.5 Literature Sources

The available literature is classified broadly speaking into the two kinds described below and ideally we only want to use primary sources.

Primary Sources – that is the first published documents. One can be really pedantic and say the real primary sources are the author's manuscript or autograph but these days we are satisfied with published sources. It will however, often be difficult to establish that something is indeed a primary source.

Secondary Sources – in almost every document you see, there will be elements attributed to other authors – these are then secondary sources.

Be careful not to confuse the above definition with those for primary and secondary data. When we talk of primary sources we are obviously referring to something that is published and exists whereas with primary data it will not exist until a researchers defined, locates and collects it.

5.6 Basic Writing Rules

For Study projects a full literature review will be needed but for Engineering projects the requirements document forms part of the Literature Review. However, even in Engineering it is necessary to write a short review just to form a technical backdrop to your project. It may help you to remember there are two cardinal rules when writing – they are simple:

Respect – always have a deep respect for ones readers and make it easy for them to understand what you are saying.

Need - only quote, paraphrase or summarize when it clearly adds to what one is saying. The key task is to formulate ones own ideas, in your own words but one does this by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

5.7 Literature Assessment

When assessing this element the University will look at how YOU use the sources in what you write and at the range of sources that you used. If either is judged deficient your work may not be accepted as the view taken will be that you are not prepared for work at this level and on this topic. It is expected that all your sources will be mostly primary ones. If there is some reason why this is not possible it must be discussed with the Research Methods tutor or your project supervisor.

5.7.1 Literature Review Structure

All the following steps are iterative and you must expect to go backwards and forwards many times before you get a review with which you are happy.

List – Make a list of all the various topic strands that you need to know about. It may help you to think about strands such as: organisational, administrative, functional, social, technological, cultural, ethical and so on or some other structure best suited to you topic. Remember, this is not about writing down everything you know it's about giving your readers a focused discourse on your chosen topic area

Arrange – Use your prepared list above and put the topics into a logical and progressive order.

Theme – Decide on a theme that will link all the various topic strands together.

Structure and Content – Now use your themed list of topics and structure what you write using headings, subheading, paragraphs, bullets, tables, diagrams and so on.

Reading/Writing with the Intellect - This is normally thought of as a four stage process that applies equally to what is written (because it is going to be read by someone).

Understanding – this is simply taken to mean that we understand the words used.

Interpretation – are able to find meaning in the words used.

Evaluation – we ask does the meaning have any value – in essence we ask is it true or false.

Contextualization – this implies that everything we read is coloured by what we already know. This idea is taken much further in the idea of hermeneutics (see the notes).

Usage – the literature that you find and evaluate can be used to supplement your own work and demonstrate your mastery of the topic area. This does not mean that you quote, paraphrase or summarise everything you see. As a rule of thumb: only quote, paraphrase or summarise when it is necessary and it is not common knowledge and it is not an obvious observation.

Argument - Finally, keep in mind that when writing you are dealing with a form or argument where you are trying to persuade your reader about some point or other and that should only be attempted when you are knowledgeable, the argument is essential and you have a deep respect for your readers.

5.7.2 Literature Review Construction

Here is a plan that you can use to construct your own review. It is not infallible and will require conscious effort from you and it must be based on a thorough evaluation of the literature.

Step 1. Purpose - the purpose is to fully prepare your mind with all that you need to know about the topic area and the particular element of it that you are focusing on. The idea is that what you write shows your mastery of the topic and in fact you have become an authority on the topic area. So a review is not a long list of quotes, paraphrases and summaries, it is an evaluatory discourse. That is, readers will want to know what YOU have to say based around what you have uncovered in the literature - so readers must see what you have found and see what you have to say about it.

Step 2. Topic and Aspect - Make sure you are clear about your topic area and which particular aspect of it you need to explore and understand in order to be able to effectively carry out your planned research.

Step 3. Select a Theme - Use your project problem definition, target and outcome to guide you in selecting a theme that will connect all the various elements of your review together making it a lucid and progressive discourse. (Don't be afraid to alter the theme as you go along if that becomes necessary)

Step 4. Your own Views - Try to make a list of your own views, ideas and knowledge. Remember, the review is an evaluation of what you find not a recitation of it. If all you do is tell us what you have found you may not even pass because almost anyone can write a review on any subject if all that is required is to more or less recite what has been found. So you must structure the review around your theme and your own ideas and thoughts.

Step 5. Make a Review Content list - Based around your theme make an outline list of things to include and then arrange the list into an order that will take you progressively through the topic area aspects. Commonly it is found that it is useful to start as follows.

5a. Basic definitions and terms that need to be clear for the core topic area. (Be careful to note any abbreviations)

5b. Map out several important areas or problem space dimensions. Now it is impossible to be general here so for example if I were looking at mobile devices and their use in business I might map out the following elements: value, attitude, use, limitations, practice cost, ease of use, learning curve, effectiveness and so on. Please be careful here to look for significant things not just drag in anything and everything. Once you have made this list you may add to it, modify it or discard from it as you go along.

5c. Work out how you want to end the review - often this just sums up your point of view but you may have other ideas

5d. You may like to include some statistics if that is relevant. But don't let this run away with you and so the review just becomes some sort of justification based on statistics. Remember, statistics almost never tell us anything about the topic itself and only tell us things related to the relative importance of certain things we have identified.

Step 6. Literature Searching - Armed with your theme and list of elements now start your search for suitable material but be very careful to record the exact details of where everything may be found and checked. The search may start with the Internet or a special tool like Google Scholar but must move on to respected publications.

Step 7. Structure - The step is to structure what you have found and what you want to say about it so we get a coherent and lucid discourse on your chosen subject area. This is not a trivial matter and you must expect to go over it many, many times before it is really an example of your very best work.

5.7.3 Literature Review Traps and Pitfalls

Most of the things listed below are regarded as due to simple laziness and so are unforgivable in a Master's student or indeed any research student and if you are guilty of them then expect severe punishment in terms of loss of marks or failure overall.

Not a justification - A literature review is NOT a justification for your research idea or problem definition. So filling the review up with various statistics will never be regarded as explaining to the reader the topic area and your evaluation of it.

Statistics - Filing up the review with statistics carries no real value in convincing the markers that you are master of that topic area.

Poor Structure - where the review is little more than a few drafts notes obviously written without much thought. To communicate you must impose some structure on what you write else the readers will not be able to see any progression in your thought or in the topic.

Filling up the review with citations - one after the other with no student input. It is correct and desirable to tell your readers what you have uncovered but unless you make comments and add your own views on what is found the work will be regarded as worthless.

Common knowledge and Obvious - Quoting or paraphrasing material that is either obvious or common knowledge implies that you have not looked at the sources beyond the first page or forward. Here is an example from a project document. "Poston (2000) stated that organisation expected ERP systems to deliver improved performance". This is worthless as it is obvious that they would want this and to say it make no valuable point at all - its no good trying to say things like this as if Poston was enunciating some law of the Universe or a point of huge importance on some new and valuable angle related to ERP - no he is just stating the obvious.

Bad citations style - It is very common unfortunately to see the citation form (Briggs, 2000) placed at the end of a sentence or paragraph. When we see this it can ONLY mean that all you have done is paraphrased, summarised or copied that section. This practice is more or less plagiarism and is representative of a very lazy attitude that assumes that just expressing something in your own words is a valuable contribution - its is not because YOU are saying nothing and what you are supplying is not really your own work at all.

Activity Definition - Some students use the Literature Review to tell us what they are going to do in the research. This will result in a zero mark as what is to be done is covered in the Research Design so repeating it here is valueless. This practice is a certain sign of laziness.

5.7.4 Reference and Bibliography

References are to primary sources that you use in the text of your written work. A bibliography is a list of sources you have identified as useful, including references, but not necessarily used. The University will look very carefully at any references to see if you are prepared for study at Master's level in your chosen topic area. Overall, the expectation is that you will list at least 10 sources. For each source you must consider its:

Currency – looks at publication date and be aware of changes in technology.

Completeness – Make sure you are looking at the final version not some draft or abstract.

Uniqueness – is the source a primary one

Coverage – Use your list of sub-topics to ensure that you cover all the areas required so that you are fully prepared. But make sure that you are not including multiple texts with essentially the same content.

Range – Make sure you have a good range of authors.

Authority – ask is the text authoritative. This can be done by considering the author, publisher, writing style and currency. It is also possible to use citation indexes to see how often the source has been used.

Accuracy – Is the information correct? If you cannot be sure then you must not use it.

Relevance – Make sure that your sources are relevant to your project topic.

Usage - The basic usage strategy is:

Find – Relevant texts using a library index, the internet, online book stores and so on.

Evaluate – Once you find a possible source you must evaluate it for content and relevance.

Contextualise – that is fit this new source into your personal knowledge base.

Cite – If you use a source it must be listed in your reference section and cited in the text correctly.

Discuss – You may include something from a source in your work as a copy (quote), paraphrase or summary but in all cases you must introduce it, comment on it at cite its source.

5.7.5 Evaluating Internet Resources

When using internet resources it pays to be careful and always sceptical because of the following factors:

Anarchy - anyone can publish just about anything on the Internet

Validation - authors do not always have their materials checked by an authoritative third party

Tendentious – when the author wants to convince you of something use any means to do it.

Honesty - authors may not always be what they seem and may assume personas, lie or make false claims

Consider – the motives of those who publishing on the Internet

Trust - in research trust nothing until you have good cause to do so. This is the opposite of what we do in our daily lives in that we tend to trust until we have reason not to

Context – be aware of the context of what you find. For example is it a University site, is it a manufacturer and so on.

Accuracy – this simply mean is the information correct. You need to be aware that information might be validly collected but still be quite inaccurate.

Validity – this simply means that we ask is this a valid source in the sense that it was constructed in a reliable manner. Any lack of information on proof readers, editors and publishers means that mistakes are more prevalent than in print and therefore increased scope for innocent error and for outright deception.

Authority – this means was the author competent to create this material. For example any one could have an interest in say Emotional Intelligence and quite easily create an internet article on that subject but it would not have the same authority as that of a University professor who has spent years researching the topic.

Uniqueness – here we are asking is this an original work (a primary source)

Completeness – this may simply be described as asking if the work is the final and finished version. You need to be very careful here else you might find your self using the material from the earlier part of the work which in fact is augmented later in the work.

Coverage – this means what is the scope and scale of the source. Now this does not mean that a source will cover everything on a given topic but it should be clear as to what it is covering.

5.8 Citation Examples

The following set of examples is intended to show some poor use of citations and also some sound ones. These examples should be studied with care by students so that they may avoid inadvertently fall into the trap of using poor scholarly practices. The quotes are from a range of sources and topics and in your study of them you need to concentrate on the form. Now assume all the following were all written by the Research Methods tutor so the comments will be offered in the first person and he is talking to you

These are just simple examples and they do not imply you must use italic or indenting as that is only used here to show clearly the pieces of work being looked at.

Example 1.

Lyau & Pucel (1995) found a link between training and productivity for their sample of Taiwanese car part manufacturers. Bartel (1994) found that training is a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors. Bishop (1994) and Barron, Black & Lowenstein (1989) both found that training increases management estimates of productivity.

This is poor because I only told you what the cited authors said. I did not introduce the author's words, nor discuss them and it's almost impossible for you to see what point I am making other than the obvious one that productivity and training may be linked – in effect it is not my work at all and there certainly is no sense of evaluation here.

Example 2

It has been found that because Arabic words were written by copyists who did not use vowels that over time the meaning of some words has been lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. One way to deal with this is to use assonance and in this paper that approach will be taken (Noldeke 2003, p45).

The problem is that it looks as if I attributed the entire paragraph to Noldeke. So you can have no idea which part of the paragraph was my own thought or maybe none of it was. This is bad practice and some tutors even regard it as blatant plagiarism. The fact is that tutors when they see this form in will automatically assume that all the student has done is paraphrase what he has found and none of it in effect is representative of any student thought and will mark the work down because of it

You can use the bracketed form if you just want what amounts to passing reference to a source as in the following example.

In two recent works (Harding 1986a, p.80; 1986b, p.138) it has been suggested that ...

Example 3

St. Clair-Tisdall (1994, p45) said in his seminal paper on Organisation Synergy that "change in organisations is an inevitable consequence of growth" – this is an interesting observation and implies continuous IT progression and updating. Knowing this we can support Briggs (1999, p23) who said that OO is now routinely used in the computing industry.

This is poor because the first statement by St. Clair-Tisdal is clearly obvious and that by Briggs is common knowledge. Also it is not entirely clear that the second sentence leads logically from the first one. The point is that using citations here was unnecessary and therefore worthless.

Example 4 - Suppose you come across the following in a book by Noldeke. But the bit that interests you is by Frederickson – how will you set about properly using and referencing the Fredricksons quote?

Tools are needed if we are to measure software quality in a meaningful way. The idea of quality, as we know, is intangible since many views are possible. It follows that we must define some terms in order to measure quality. It is useful to note what Fredrickson said: "Definitions of what quantities we need to measure in order to assess software quality are at present arbitrary since as far as we know they have no connection with functionality".

This does not mean that they lack a rationale, but simply that professionals disagree on the definitions themselves and so it follows that

In this case the correct way is to find the Frederickson book and use that because it is the primary source. Quoting from secondary sources will only be tolerated in proven cases where the primary source cannot be found or for other reasons is inaccessible and it must be done in the correct manner as shown in Workbook 8 for secondary sources.

Example 5 – Can you work out what the following extract from a piece of student work is saying – if you can please tell us in simple words

It is argued that tacitness, complexity, and specificity in a company's skills and resources can generate causal ambiguity in competency-based advantage, and thus raise barriers to imitation (Fahey, 1989). This is to rise a company's distinctive strategic positioning so as to possess some form of sustainable competitive advantage.

The sentences is obviously copied as it is very, very unlikely that any student would write with such academic complexity and obscurity – lines like this are not designed to communicate they are designed to impress the reader not further his understanding. What it in fact it is saying is that some skills are very difficult to duplicate and this may mean that growth may be restricted.

Example 6 – Here is a good example and in this case I paraphrase the idea rather than use quotes. Notice how I: introduce the idea, state the idea and discuss the idea and so I weave into quotations, paraphrases, summaries or whatever my own words and thoughts and evaluations.

There has been a long standing problems with some early Arabic manuscripts in that many words have become obscure and even in context they are still unclear. Bigly and Ahmed (1978, p340) and others have shown conclusively that because Arabic words were often written by copyists who did not use vowel, over time the meaning of some words became lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. It has been usefully suggested by Noldeke (2003,p87) that one way to deal with this is to use "assonance analysis" to study word endings and in this paper that approach will be taken and in particular we will look at some early Arabic poems by Averroes.

5.9 Literature Reviewing Cautions

Writing a literature review is a difficult and time consuming task if it is to be done well and there are no short cuts to sound scholarly work so here are some final pointers.

Laziness - It is very common to see students write down things in a literature review as they occur to them. This practice might be fine for notes but it is obvious that the way thoughts pop into ones mind or information is discovered is most often anything but logical or structured.

Structure – to communicate in writing the work must have an effective structure that is well planned and allows the theme to develop to it natural conclusion.

Pretence - some students try to be scholarly and pack their work with quotations and paraphrases – this then become not an evaluative review of what was found but a recitation of it instead.

Non Review - some students just write down what they know without any references to the literature – this will always lose you marks as no one will believe that you obtained that information by your own brainpower without any outside assistance.

Experience – students often claim that what they write is all down to experiences but again no one will accept that. They way you use experience is in your evaluation of the sources, comments on them and building up your own arguments.

Inclusion – Preparation of the mind for your topic area does not mean you write down everything you know that might be relevant. What it does mean is being focused on your topic area and becoming expert in that. For example, an Engineering project where the literature review contains page after page devoted to telling the reader about every conceivable life cycle is hopeless and in such cases there is almost no thought over what is written and so it is worthless. Similarly, if a study project was looking at eCommerce as a way of selling drugs then page after page telling us about various drugs, treatments and prescribing practices is worthless in the context of just selling drugs. It's not volume is wanted but considered content.

6. WORKBOOK 6 – MAJOR PROJECT ELEMENTS

This workbook is intended to help students formulate clear project elements but here that what is said here is a mechanical process and it is your responsibility to make sure that what is written down makes sense.

6.1 Scope and Scale

Scope and scale are meant to be considered carefully otherwise a project which is out of control and way beyond your capabilities in the time available may occur. Alternatively, the scope and scale may be set so that the problem becomes trivial and the idea is rejected. So please take note of what these terms mean as far as this course is concerned.

Scope – this means something like selection or choice. So for example, if I were looking at training in desk-top packages I might select just Excel or I might select Excel and Access and so on to focus on. The point is I set my scope by being selective.

Scale – the means something like number or extent. So for example if I set my scope as looking at Excel I now need to set the number of users I will include in my study.

Scope and scale are two dimensions that set a frame around your work to bring it into sharp focus and exclude everything else. You need to put limits on both these dimensions but it is most important is to be clear about scope – that is, what exactly to include in your study, normally, just include ONE significant thing.

6.2 Presenting Problem

In any project it is usual to choose an area of knowledge and practice to be its topical focus. For example, one might choose modern usability issues, automated network management, digital paper and so on. Once one has a topic area like this it is necessary to choose a problem theme within it to be a sharp focus for a primary data research effort. It is best if one problem theme is chosen and its resolution or partial resolution would be of strategic business IT significance. In general, it is not all that easy to give a simple and all embracing definition of the notion of problem but the following has proved to be useful.

A problem or issue is something that is a matter of concern or debate within the topic area and whose resolution might bring benefits. (Checkland 2003)

In practice this means a problem is an object not an activity. For example, stating the problem as “how to ride a bicycle” is incorrect since this is not the problem it’s a question about the problem - the problem is “riding a bicycle”.

Another difficulty is that students often write down the problem in such a way that it is an answer or solution to the problem. So for example, if one writes a problem statement as “lack of training” then implicitly that is a solution as well. When this happens it is almost certain that the writer is not thinking about the problem at all but is obsessed with a particular solution. In this particular case the real problem might have been “errors in data entry” and one of many possible solutions is training.

6.2.1 Defining the Problem

It is always quite a good idea to construct one's own definition of the problem and to do it in as few words as possible. Notice, that it is your own definition not one you might look up in a book or on the internet (though you might start with that) because there is often little learning value in just copying a definition as far as deepening your own understanding is concerned.

Remember, that any definition one constructs will not be absolute and universally accepted by everyone - but in research this is not a problem as long as the researcher makes it clear what particular definition is being taken. Do not take this process too far and end up with either over-complicated or trivial definitions - they must be thoughtful and comprehensive. So it is recommended you start by thinking about four things where the acronym CAPE is used:

Characteristics – observable features or facets of the problem idea,

Associations – every problem will have links to other situation elements,

Perspective – when a problem is encountered it will always be from a certain perspective

Effects – say what effects ensue in the real world if the problem is not resolved.

6.2.2 Defining the Problem - Example

Let us suppose that a student has identified the problem theme as Phishing. Naturally, the student will be concerned that this is a good idea and would like confirmation of that before expending time on it. One can

ask the course tutor, but he/she is not expert in everything so at best one would only get an opinion as a response so how should a researcher proceed. So for Phishing a researcher might note the following:

Characteristics: illegal, intrusive, upsetting, preys on those who trust their fellow man, etc

Associations: email, chat, file sharing, etc.

Perspective: management (but try to look at it from several perspectives as well)

Effects: destroys confidences in the system, may lead to personal or company losses etc

Normally, it takes quite a few attempts before a definition that is lucid and comprehensive is obtained. Remember, the definition must also be useful within your research study – that is, it's no good having a well formed definition that does not offer a sound basis for a research effort.

Now here is a first attempt

In the modern world email is a technology that almost everyone uses whether in the home, at work, on the move and indeed it seems to follow one around. Typically, email is a simple one-to-one message passing technology but it is now offered with enhancements that include voice, video, chat, file passing, file sharing where suppliers are attempting to present a complete communication environments. With such a technology come problems and one such problem is identity theft and one way of getting this is known as Phishing. In its simple form an unknown, but apparently authentic, source asks for personal details and then uses them for fraudulent purposes. The problem is identity theft using email systems where a message poses as a legitimate requestor in order to fool the recipient into thinking it is legitimate request. The problem in computer system is known as Phishing.

Here is a final attempt (but most often there are several intermediate attempts)

Phishing is identity theft using email where a personal message seeks confidential or private information from its recipient whilst posing as legitimate request. The intention therefore is to fool the recipient of the message into releasing information which can subsequently be used for fraudulent purposes.

6.2.3 Cautions on Problem Definition

The acronym CAPE is just an aid to formulating a definition so one should not worry whether something is a characteristic or an effect - that does not matter very much because the whole idea is to uncover problem aspects and expand one's understanding of the problem theme.

As a very rough guide one often finds that the final definition must come down to about a third of what we start with. In most cases if one is familiar with the subject it is possible to create a good definition in about 1 to 2 hours and then if necessary update it as your project progresses as it is almost certain that there are elements that have been missed or imperfectly understood.

6.2.4 Problem Size

It is hard to measure the "size" of a problem because there is no scale on which to gauge it. But one can look at two aspects to get some idea.

Current Effects – think about the effects of the existing problem and try to assess their seriousness in terms of the context in which it is set. In simple terms just ask "is it worth solving".

Form of Answer – perhaps a better guide is to think about the form of answer and see how extensive, important and how hard it is to get. For example: one student wanted to deal with password overload – a clear problem with which we are all familiar but his outcome was a set of guidelines on how to construct good passwords but in my view that was a trivial answer to the problem because those guidelines can be found almost anywhere and it is doubtful if that goes anyway to solving the overload problem.

6.3 Project Target

When you think of a problem you normally do it in relation to its effects. It follows that you have to think very early in a project about what effects will be generated if you can resolve the problem – these real world effects are called the project target. Normally one settles on one major target although it is permissible to list more than one. Targets are effects so these are typically introduced by a verb form (increase, reduce, remove, reduce etc) and tend to be such things as: improved accuracy in data entry, to gain infrastructure resilience, streamlined workflow and so on.

6.4 Project Outcome

It is obvious that at the start of a project we do not have its outcome – but we can have some idea what its form may be. Therefore if we know our target we can speculate about what could be generated as a project outcome that might generate or go some way to generating the desirable target. It follows that whatever we

decide is the form of outcome we are looking for in the MSc project it must credibly be able to generate the stated target. Outcomes are objects and so are typically expressed as nouns: Here are some examples:

The target of “improved accuracy in data entry” might be generated by a project outcome of a training needs assessment report or a training plan.

The target is “to gain infrastructure resilience” might be generated by a project outcome of a revised backbone design or a set of recommendations for new technology.

6.5 Problem, Theory (Speculation) and Form

It is often useful when thinking about the solution to a problem theme to think of it as based around or generated by some personal theory a person holds about that problem and its setting. Essentially, one gets at this theory by speculating about causes and possible solutions routes. It is not easy to say how to speculate but it can be said that it is aided by a thorough literature review, personal experience and a deep consideration of the problem theme perceived in a given situation.

For example suppose the situation was related to issues with application software implementations in business not being as successful as expected. Recognition of this problem theme is a first step but if one is to do something about it, it might be useful to thoughtfully speculate on why success is lacking in this area. It follows that one might speculate that this lack of implementation success is due to poor implementation strategies, or poor user training, or poor project management or any number of things. Notice that there will always be rival speculative ideas and that is why one must be thorough in looking at the literature and using your basic knowledge and experience to open up the situation in order to at least have a credible theory as to the most probable solution route otherwise one might just waste time on chasing nothing of value.

Do not let this idea run away – this is not about natural laws of the universe such as Ohms law or Archimedes Principle – here one tries to establish a personal belief about a situation and its problem theme. So after speculation one might express ones personal theory about the above example as follows.

It is believed that implementation of application software is proving difficult and this may be due to poor implementation strategies. It follows that if this is the case and better strategies can be defined then implementations may prove more useful in the future.

Notice that my theory points to a particular form of answer to this problem theme and in this case it is related to perhaps a document that explains how to formulate implementation strategies based on a consideration of user needs, application intention and business objectives.

Occasionally, the theory may be embodied in a scientifically constructed hypothesis but more often than not in technological research it is expressed informally as an idea.

6.6 Primary Data

Primary Data is data is new data in the sense that it will not exist as a collection until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data collection is representative of some aspect of the area under investigation and can be processed to get a defined form of outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

6.6.1 Primary Data Collection Protocol

Within every project there has to be a collection protocol for the practical collection of the primary data. Every complete protocol will have 5 features:

Vehicle – this is the primary mechanism or technique employed by the researcher, typical examples are: interview, questionnaire, observation, role playing, seminar, focus groups, document searching and so on

Recording Profile – this describes how the data will be physically recorded. Typically we might use: written report/transcripts, formatted record sheets, video, sound recording, computer logging, excerpts from documents and so on.

Sample criteria –this is a profile that allows the researcher to know that he/she has a valid sample point from which data is to be collected. For example, if we wanted data on business uses of Digital Paper we need a profile of who we should ask for that information. If we do not have a profile we may not have any consistency in our data and it may therefore be meaningless.

Permission – you have to feel certain that the information you seek is legitimately available to you.

Ethical Profile – you need to be clear as to what you are doing, the way you are doing it and what you are asking for is ethically acceptable. Two things are at stake: the results may be biased and the results may not be acceptable.

6.6.2 Project Purpose in a Nutshell

Students sometimes get confused over what a Master's project is about. Consider a topic area like Digital Paper which is likely to be a very hot technology in 2006/7. A Master's project is not about producing a long narrative on Digital Paper explaining what it is, how it is used and what the technological infrastructure to support it might be. A Master's project is about identifying a problem theme in Digital Paper and then collecting and processing primary data into a form that helps you resolve that problem theme based on ones own personal theory. With this in mind, consider the following examples.

Example 1. Suppose I want to define all the various accounting functions so I pick up a manual for my in-house accounting system and then go through it looking for all the various accounting functions and listing them – is that primary data and is this a valid research purpose? No because in the first place one might just regard the manual as listing the functions anyway so in effect the data already exists, secondly, this is just one book and so its content might be complex, trivial or totally unrepresentative.

Example 2. So if I extract (my basic activity) instances of phishing (my problem theme) from an email log that would be primary data because even though the email log (secondary data) obviously exists, the list of phishing instances (my primary data) as a collection did not. My purpose being to process this collection of primary data to find out the most common sources of phishing and express my findings in an evaluatory report (my form of answer).

Example 3. If I conduct interviews in order to describe (my basic activity) a user purpose regarding illegal downloads (my problem theme) in my company with selected employees the interview transcripts are my raw primary data because the transcripts did not exist before the interviews took place. My purpose being to process this collection of primary data in order to develop a policy (my form of answer) to control illegal downloading activity.

Example 4. If I look through written reports (secondary data) on security violations (my problem theme) for a particular company with a view to identifying (my basic activity) the root cause of each violation then even though the violation reports exist the list of root causes (my primary data) did not so it is primary data. My purpose being to process that collection of primary data to create a strategy (my form of answer) that will alleviate or remove certain kinds of violation in future.

Example 5. If I plan to build an application for processing student MSc marks (my problem theme) then I need to ascertain (my basic activity) the system requirements (my primary data). My purpose being to process this collection of primary data to create a design (my form of answer) for the marks processing system.

6.6.3 Pre-processing Primary Raw Data

In many cases it will be necessary to process the raw data that one collects into a structured form of some kind so that is easier to use when generating the final project outcome. For example, if we have a series of interview transcripts it is obvious, that in that form, they are not easy to use so we might perform a pre-processing phase to get the core data into more structured form that then constitutes our primary data collection before the main processing phase that generates my project outcome is carried out. For example, suppose I examine company documents on misuse of IT system resources by employees. In this case I might proceed in two ways to get my structured primary data collection.

In line processing – that is I define my structure before I start and then as I come across a misuse example I structure it there and then. However, the disadvantage here is that you have to continually look back to see that you are not recoding the same data again and again from other incidents and so it tends to disrupt the collection process and make it longer to complete.

Pre-processing – here I wait until I have been through all the documents and then I use my set of notes to systematically work through the whole raw collection and form my structured collection that way.

6.7 Writing a Research Question (Study Projects)

This is intended to relate to the core problem that your research is trying to resolve. Make sure it is a clear question. Ideally one wants an open question: that is one that does not just end with a yes or no answer. This is often quite difficult to achieve but it can be done if you work at it.

A question is an expressions normally used to request information the form of an answer. Questions can sometimes be like commands used to elicit a response and others such as "Would you pass the salt?" looks like a question but in fact is a request or action, not for an answer. In Research Methods, however we will only look for questions that elicit information.

The simplest questions implicitly or explicitly request information from a range (finite or infinite) of alternatives and these are often called bi-polar questions. An interrogative word is a word used to start a question. In English the following is a list of interrogative words although some of them are rather old fashioned now.

Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, is/are, and can.

6.7.1 Questions that are not Questions

It is often difficult to write something that in English could be taken as a question. Now I am sure that in daily life everyone knows how to ask a question but when you write something down you are entering another world. Consider the following two lines – would they be understood as proper questions?

How to sharpen a pencil? Or What a pencil can do for you as a student?

Now these clearly ask for information but if you spoke these fragments to someone they would not quite see it as a proper question – in English such fragments would be understood as a kind of heading to a list of instructions for sharpening a pencil or a list of the benefits of using a pencil.

6.7.2 Basic Research Question forms

It is best when attempting to construct a question to think about what sort of answer is to be expected – now in normal everyday life we do this instinctively. For example, you would not say "is this the right way to Pablo's restaurant" if you wanted actual directions because that question form could only give you a Y/N answer. Instead you would probably say something like "how do I get to Pablo's restaurant from here" and reasonably you would expect an explanation to that question. Broadly speaking there are four sorts of answer:

Bi-polar answers - Essentially questions that imply a limited range of possible answers. Typically, a bi-polar question starts with a word such as WHAT, IS, CAN or DOES.

Is it possible to sharpen this pencil? (Y/N)
Does it make sense to allow children to sharpen pencils (Y/N)
Can a blue pencil be sharpened easily (Y/N)
What is the correct pencil weight for drawing a picture? (HB1, HB2 etc)
What is the common view of staff about using blue pencils? (Disagree, agree, etc)

Bi-polar questions can of course be useful but more often that not they have no great utility and the answer is obviously yes or no. Consider the question: "Can a green pencil be used in place of a red one?" Well of course it "can" be used so the answer is bound to be YES and so the question is pointless. Sadly, questions in this form occur all too frequently in student work and whoever writes such questions is not thinking at all about what information he/she want to elicit.

Explanatory answers – where the expected answer is an explanation and it is often in the form of a procedure or process. Typically, explanatory questions that start with 'HOW' or 'WHY'. For example, "How can a pencil be sharpened safely by young children?"

Descriptive answers – where the expected form of answer is a description most often in the form of an evaluation. Typically, these questions start with WHAT or WHY. For example, "What is the purpose of HB0 pencils?" (a simple explanation) or "Why are HB0 pencils difficult to sharpen?" (an evaluation)

Exploratory answers – where the expected form of answer implies an answer as an exploration of something. Typically, exploratory questions start with HOW or WHY. For example, "How should we use HB1 pencils best in drawing figures?" (often an exploration is needed here leading to an explanation)

Good interrogative words to start questions are: what, where, would, in what way, can, is it, why, which, where, how, does, who, why, do, etc – whatever word you use always ask what form of answer is implied by each of them. You must be sure that whatever form you decide on as answer that you can actually construct it and when it is constructed as part of your research it is in fact useful strategically in some way.

For example, suppose I decide that the form of answer I want is “The role of technological innovation is business success”. Well the task you now have is to now ask yourself whether you know how to express a role (write it down if you like) and whether knowing about this role will be of any use.

6.7.3 Research Question – Why are we asking it?

In normal everyday life questions come at us more or less all the time. Sometime we just answer them but more often that not we have a tendency to ask “why do you want to know”? It is therefore always useful when setting out your research question to ask why you asking it. That is you say to yourself, if I have the answer to this question then there will be some good outcome because of it. Sometimes we embed in our questions why we are asking them but mostly we do not. You will see later however, that you will have to make the reason plain in the aim so one might as well think it through at the question stage as well.

6.7.4 Research Question Form of Answer

For any Research Question there will always be several possible forms of answer arising out of ones personal theory about a problem situation encapsulated in the question. Ideally one would like the research question to be worded so that ONLY one form answer is possible and that is the one our theory suggested but often that is not easy to do so one normally has a range of options and competing theories to choose from so one looks for a form that interests you or looks to have the most utility. Do not be tempted to have multiple questions all in one sentence or look for multiple answers since it is better to focus on one significant output form. Table 4 lists the main forms of answer to help you when considering your personal theory.

Category	Typical Interrogatives	Expected Forms
Bi-polar	does, is, are, what, when or can	A list of possibilities
Explanations	how, why, who or where	A report, a model, an equation, a theory, a design, an evaluation etc
Explorations	How, who or what	A list, explanation, a comparison matrix, a pattern, a survey report, a theory etc
Descriptions	What, who or why	A report, a process or procedure, a model, a policy, a strategy, a theory etc
Table 5. Research Question Outcome Possibilities		

6.7.5 Strategy for formulating a Research Question

There is no easy way to do this and no real templates for it either so a good formulation will require some clear thinking and effort. What follows is a typical structure that you might use, but do not feel limited by it, and neither should you worry too much about the order in which you present the following elements although it would be very odd not to have the interrogative at the beginning (**SPITS** for short)

Spotlight – try to put the spotlight on where the primary data or information needed to answer the question might help come from.

Problem – this is about focusing on a single problem, so try to be as concise as you can.

Interrogative – what is your key interrogative word (how, why, what etc). You should note that some interrogatives need to use two words if a proper question is to be formed. For example, “how” on its own will not normally make a question but when you say “how can..” it is clearly a question.

Target – think about what will happen in the real world if you can resolve the problem. For example, it might be your target was to gain efficiency improvements, provide or enable better communication, increased accuracy and so on. It is also possible, but usually unwise, to state the target negatively if this makes the wording of the question more natural and you will see examples of this in section 6.7.

Suggestion – here one thinks about the problem theme and simply asks what sort of answer and what form it might take. So sort of answer might be yes/no, an explanation, an exploration, a description and these sorts of answer might be expressed at the end of the project as a report, a model, a list and so on.

Here is a good example from student work - "How can the billing cycle time be reduced by identifying and defining best practice in order to improve the quality of response to customers by reviewing the initial accounting processes stages?" Notice here that we have:

Interrogative = what, **Problem** - billing cycle time, **Target** – improved response to customers and **Spotlight** – initial accounting process and **Suggestion** – a best practice portfolio.

It is not always useful to add in the data spotlight because sometimes it can limit ones speculation about causes and solutions and in any case, the spotlight is often implicit in the problem definition. It is also possible and permitted to add in what form of answer you expect to the question but normally I would advise against that in most cases and this is discussed in the next section.

6.7.6 Function of a Research Question

The function of the research question is to crystallise the problem and desired effect (target) of any solution. But doing this is only useful if it allows the research enough room to theorise or speculate about possible answers so that indeed the solution space can be explored. Consider the following formulation:

"What factors influences the development of sound IT project management working relationships?"

Here we have in a solution because we are told that the problem is "working relationships" and what we want as a target is sound working relationships. But we in effect we are told to look for factors and so the solution to this problem theme will be a list of factors. The trouble with doing this is that it cuts off any further speculation about dealing with this problem idea and so the question becomes rather pointless.

6.7.7 Meaning in a Research Question

This section has looked at the structure of a typical Research Question but that is all it is and students must not treat it as some sort of template – it **MUST** be thought out step by step and even then one has to think does it make any sense, is it a focused question, what sort of answer should I expect and so on – there is simply no substitute for careful thinking.

Once you have formulated your research question and have a good idea what form the answer will take then its time to test it using the following ideas. Now be aware that this is just a test of structure and of itself it does not mean the question makes sense – there is no way to do that other than using your own brainpower and common sense – if it makes sense to you it will probably make sense to whoever else looks at it.

English – does it read correctly in English as a question?

Paraphrase – if it's a good question you may be able to ask it in several different ways – so try to do that until you get a formulation you are happy with.

Bi-polar – this means that the question has a fixed and limited range of answers such as "Y/N", "bad", "good", and "excellent". This type of question can of course be useful but the problem with them is that such answers do not have much utility – that is they do not tell you anything of value in terms of what action or actions you might take. You are advised to avoid such questions for your project.

Discussion – look at your question and honestly ask 'will this question produce discussion?' – what this means is to ask 'who am I writing this question for and would it interest them'. Try not to think that you are doing this for your Research Methods tutor but try to think what you would do if you were trying to get funding for research to get an answer to the question from someone.

Answer Form – try to work out what form or forms the answer will take (typically: bi-polar, explanation, description or an exploration) – if you try to avoid this aspect you may find yourself in serious trouble with your research.

6.7.8 Common Errors in Research Questions

The following are typical errors found in student written Research Questions – they can all be avoided if one takes just a minute to think through what has been asked and what sort of answer is likely.

Not a Question - to an English speaker the following would not sound like a question, instead it would sound like a heading to a list of instructions or a procedure. "How to make business application development productive at XYZ Corporation?"

Multiple Questions – It is never a good idea to try to put TWO (or more) questions into one as in the following example - one is about testing and one is about bugs they are quite different things. "How can software bugs be minimised and the testing cycle shortened in the development process of an Inventory System?"

Obvious Answer – these are cases when no research is needed because the answer is either obvious or common knowledge. Questions like this show a serious lack of thought – take the second example and it is easy to see that the answer to the question is bound to be YES - of course a productive work-life balance "CAN" (but might not) be obtained so there is nothing of any value whatsoever in a question like this. Similarly, it is easy to explain how a better development process can increase productivity.

"How can a better business application development process increase the productivity at XYZ?" or

"Can a productive work-life balance be achieved with telecommuting for technical personnel?"

Please remember that it is possible to write a very poor question that exhibits more than just one error type. Again, there is simply no substitute for thinking about what it is you have written.

6.8 Primary Data Generation with BAGeD

Based on a problem theme, theory and the form of the project outcome expected one needs to formulate a process to create a unified collection of primary data. There is no algorithm for doing this and one has to go carefully through the steps: define the data (BAGeD), locate the data and decide on a protocol to collect that data reliably.

Spotlight - The core of this primary data generation process is to find an activity whose execution effectively points to the right data so that you can formulate the whole collection plan around that activity. This core activity is called a Basic Activity for Generating Data (acronym BAGeD) and is the activity that one performs to generate the primary data that you want. Think of the BAGeD as a sort of spotlight that is focused just on the primary data that one needs and nothing else. That is the spotlight illuminates the data that you want in the sense it tells you how to generate primary data items but not how to actually collect that data.

With a BAGeD it is ideal if you can find just one verb to describe the activity. One needs to be careful here that the activity is clear since almost all verbs need to be qualified or supported by stating what the object of the activity is. For example, if I were to say, "look at fault logs for my primary data" then that is very indistinct because it does not tell us what to look for (the object of the looking). But if I say, "look at fault logs to describe instances of SPAM attacks" then I now have a more distinct activity because I know what I am going to write down as my primary data. The whole primary data collection process is then fitted around the BAGeD and the detailed planning to get the necessary data can then be made.

Example - suppose the problem theme is the value of training. Clearly a lot of money is spent on training so it might be really useful to know if there is a link between it and productivity. Suppose we speculate that the link is to do with essential business working practices and these change over time to meet new needs so that what I need is an answer in the form of a process model on how one identifies changes in business essential working practices and links them to a training initiative.

Now that I have my theory and form of answer (a process model) the Basic Activity for Generating Data can become **describe changes in essential working practices** of key operational staff – thus, my Basic Activity is "**describe**" and the Primary Data will be **changes in essential working practices**. In practice you might try several ideas before you are happy with one. Now I have this core activity I can work out the full process of getting to the data and processing the resultant collection to get my process model (outcome) that describes the link between business essential working practices and training.

Once the BAGeD is clear it, is an easy step to say how that data will be collected. In the above example I might use interviews with relevant staff. In summary the whole process becomes **describe changes in essential working practices** (BAGeD) using **interviewing** (collection protocol) with relevant staff.

6.9 Getting a BAGeD

The Basic Activity for Generating Data (BAGeD) then is an idea that allows you to spotlight exactly the data that you want. So we are looking for an activity and we hope that activity will shine a spotlight on the data. There are only three real considerations:

Problem Area Expertise – it is obvious that you need to have gained expert knowledge in the topic area and in the particular aspect related to the problem theme you are dealing with. In general, depending on the topic, this might include things such as: knowledge of the technology, management and usage processes. Unless you have thoroughly prepared by using literature reviews and/or other means you will simply not be in a position to know enough to be able to decide competently what data it is possible to collect.

Intended Outcome – fix in your mind what your Research Design is trying to generate as an outcome. With the above in mind, recall that whatever data you collect will be first formed into a structured primary data collection during the pre-processing phase, which follows immediately after collection, and then that structured collection will be used to generate your outcome.

Let us suppose the outcome is to be a set of guidelines, so you have to think what sort of primary data is needed to be able to generate the guidelines. This means you must know what guideline means and how one is constructed and that is where secondary data comes in. So in this case you might look at text books or journal articles to find a guideline model to use. Additionally, you would look at examples as well as look at any relevant company or international standards.

Collection Protocol – the last thing to consider is can the data be collected and if it so, what is the best way to do that. So it's not a matter of just choosing anything that comes to hand, it is a serious practical consideration based on a thorough and logical analysis of the sort of primary data that you want.

In the guidelines example above, the idea might be to use a questionnaire and one has to ask would a questionnaire allow for the collection of the data I needed. Let us suppose that the data we spotlight is: IT media and usage. Now it's obvious that a questionnaire can easily get media data but it is not clear how it could capture usage data so I might decide to get that information by interview instead because I want a much richer picture there. The point is that guidelines are largely about usage so that is where I must direct my effort.

To elaborate, usage is a complex issue and if you try to get it with a questionnaire you are going to have to have a very good idea what the usage processes are and so it may miss lots of things that are going on in the company setting. Whereas, if I use an interview, I have much more opportunity to explore the usage idea and that is what I really want.

6.10 Research Question, Form of Answer and BAGeD Examples

Consider the following further examples which focus on the BAGeD (your data spotlight) and linking it with some theorising or speculation about an expected form of answer. In each case several possible forms of answer are listed but in a research study only one would be chosen for further work.

One needs to be careful – this all sounds fine, even clever but a researcher must seriously consider if a complete process built around the BAGeD can be formulated in order to get at the necessary data within the time and other resources that are available.

RQ = What limits investment into e-applications for SMEs in Hong Kong leading to a loss of competitiveness?

- A list and description of investment constraints or
- A strategy to deal with the investment constraints or
- A feasibility report on e-application implementation or
- A post implementation review report or
- A prediction reacted to the effects of the constraints

Let us suppose that I choose a list and description as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on reviewing investment plans and the corresponding strategic plan in order to identify (Basic Activity) the possibility of an investment constraint (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to collect investment and strategic plans (secondary data) and by a process of review I identify and extract key investment decisions in the investment plan linked to a strategic plan. So my primary data will consist of a list of identified investment constraints, which I will need to explain.

RQ = How can IT operational criticality be monitored and controlled in order to build effective business systems?

- A process of data criticality categorisations or
- A user guide to data criticality or
- A DRP/BCP policy document or
- A report explaining how data and criticality are related

Let us suppose that I choose a DRP/BCP policy document my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on listing data categories and using these categories I review reported critical incidents related to data categories in order to match (Basic Activity) the category to the criticality of the incident (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to collect category data (secondary since they must exist in this case) and collect incident reports (secondary data) and by a process of evaluation of each report extract incident details and categorise them (my primary data). So my primary data will consist of a list of categorised critical incidents.

RQ = How can supply chain logistics be improved to provide continuity in manufacturing systems?

- A evaluation of a modern supply change process or
- A feasibility report on RFID or
- An implementation plan for RFID or
- A model that shows how improvements may be made using RFID

Let us suppose that I choose a list of implied benefits all explained as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on describing (Basic Activity) supply chain tracking problem themes (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to identify tracking problem themes and by process of evaluation of each problem theme I analyse how RFID might alleviate that problem theme. In essence I extract key reported problem themes and possibly categorise them (my primary data). So my primary data will consist of a list of categorised problem themes in supply chain tracking.

RQ = How can an improved personal communication protocols be established leading to productivity and business success?

- A feasibility study on IM and its use in offices or
- The definition of a training programme or
- A series of factors that must be in place before IM adoption or
- A cost/benefits report or
- The design of a regular monitoring scheme to assess effectiveness

Let us suppose that I choose a cost/benefit report as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on analysing (Basic Activity) call content with regard to costs (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to identify the sort or calls and then extract the cost (easy) and assess the benefit (hard) and by process of evaluation arrive at my report. So my primary data will consist of a list of calls and their associated cost and benefit.

6.11 Writing an Hypothesis

This matches with your research question and amounts to you saying what you think to be true in a given situation. It is in essence an extension of your form of answer where you try to say not only the form but what you think the answer will actually be. When you do this your work then become a process whereby you try to show that your hypothesis is valid. It is quite difficult to write a suitable hypothesis. There are three stages: firstly write the null hypothesis, secondly write the alternative hypothesis and lastly write down the dependant and independent variables. Unfortunately many new researchers seem unable to do these things satisfactorily. Let me illustrate.

A student wanted to write a hypothesis that essentially said that there was a link between IT certification training and personal productivity in support roles. He then went on to define the variables as: Role of IT (independent) and Personal Productivity (Dependent). Now this will ONLY makes sense if you can quantify the variables productivity (which is quite easy) and 'Role of IT' which it seems cannot be quantified. Now in research people tend to treat the idea of hypothesis in two ways and the second way is often quite valuable in many research situations.

6.11.1 Formal Experiment

To set up a formal experiment one creates or identifies two samples: one exposed to some effect and one not. For example, suppose I were looking at whether a new diet called lose-weight-quick worked or not. I could set it up a hypothesis and look for samples where some people were exposed to the new diet and some were who were not. The experiment then amounts to seeing if there is any significant difference between these two samples. (See notes for how to set up a formal hypothesis)

In a sense we are trying to prove the diet works but that notion of proof needs very careful understanding. The point is that it is very likely that the diet will work for many in the sample and not work for others. So our proof carries a qualification which is that all we could reasonably say at the end is that the diet is likely to work for a large number of people (or not as the case may be). A second point is that we do not usually do thousands of similar experiments and so at best our results for a limited sample would be tentative. Notice that this outcome is quite different from an experiment that sets out to verify a natural law like Archimedes principle or Ohms law where the amount of variety is much, much less and of course such natural laws have been tested many thousands of times so we are assured of their validity.

6.11.2 Informal Idea

Instead we could just have what might be called a tentative hypothesis that suggests that there may be a link and then use case studies to demonstrate this. Notice that we are NOT proving anything here only suggesting that something may be true.

6.12 Writing an Aim and Objectives

For each project we want one overall aim and a set of objectives that collectively will generate the form of answer that has been defined (project outcome). An aim/objective is expressed as an activity to get to a defined and measurable outcome within the scope of the project. The essential difference is that the aim expresses the target (or purpose) for the whole project outcome whilst objectives perform the same function within the project itself. Every time you write an aim or and objective you have to ask three main things with the abbreviation JOB – so when you write an aim or objective make sure you do a good JOB of it.

Can Justify – this really amounts to asking if the aim/objective make sense in that it generates a minor project outcome within a particular aim.

Can Observe - Make sure than someone else can observe or check what you have done, normally this means you can document it in some way (in words, diagrams, charts, graphs etc) in your project document. For Engineering projects this also means that the application is visible to all markers.

Can Build - Make sure that YOU can build the outcome stated.

6.12.1 Project Aim

This derives from the project problem definition and is best thought of as expressing the overall activity and intention of the project to generate an outcome that can be placed in the project document or made easily visible to the examiners. It has a number of elements as follows although when you write your aim you do not have to do it in the same sequences as expressed here and you may write it in any way that best captures your ideas although doing it in this sequence tends to be more logical.

You will note in the aim structure that follows that the problem theme is not explicitly mentioned and we infer what it is by looking at the target. The reason it is not included explicitly is that when one does one tends to get very awkward constructions linking problem and target so we might see absurdities such as “to improve website accessibility because web site accessibility is problematic”. The structure of a good aim is as follows where we can use the acronym ASOT to remember it.

Activity – what must be done with the available data to get the project outcome? Ideally, look for a single activity that sums up the whole project process for generating the intended outcome.

Spotlight – where will the basic data used by the activity come from?

Outcome – this element says how the project outcome will be expressed knowing that this outcome will later be used to generate the real world target. If the Research Question expects a model as an answer then the aim must have the same form of generating the model. Similarly, if the application description states a system to do X then the aim must have the intention of generating system X.

Target – what is the real world intention? That is the project outcome should be useful in the sense that it addresses the real world problem theme on which the project is based.

Aim – to create a website structure design using cascading style sheets in order that it might be used in design to improve web site accessibility.

Activity = create, **Spotlight** = cascading style sheets, **outcome** = web site structure design and

Target = to improve accessibility.

Sample Aim 1 – “To create an improved network infrastructure”. This is unsatisfactory because we have no target - we know that there will be an improved infrastructure but we don't know what effects that will have. So is improved infrastructure the outcome – it cannot be because it would imply sending to Portsmouth for marking some object called “improved infrastructure” and that is an absurdity. So here we have no target and no outcome and we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

So if I just use the above example it would be possible to have a target of a reduced network down time because of the Improved network infrastructure but that could ONLY happen after the project completes and in the project one could generate an infrastructure design - now that can be completed within the project period and later used to build the infrastructure which can then be used to generate our reduced network down time. Another factor here is that we cannot measure whether something called improved network infrastructure (what scale would we use?) has been achieved unless we have a target such as reduced down time which of course we can measure.

Sample Aim 2 – “To build a Wi-Fi implementation strategy”. This is unsatisfactory because although we know the project outcome is an implementation strategy we do not know what value it has in the real world because we have no target. Notice also we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

6.12.2 Project Objectives

The aim expresses the overall outcome for the project but to get there we normally have to pass through a number of minor outcomes on the way and these are expressed as being generated by objectives. For example, an objective that sets out to build a model of the software construction process could easily be a minor outcome for a project dealing with the construction of web sites but could also stand on its own in the sense that is a useful outcome whether the project is completed or not. Conversely the design of a set of interview questions is most likely not to be an objective but a simple project task since it is something that needs to be done but only has meaning within the project.

Since we are looking for minor project outcomes that collectively deliver the project outcome we have a little problem here because any project is made up of a series of tasks, some of which will generate a minor project outcome and some will not. For example project tasks range from preparing the contents list to evaluating the project outcome. A possible rule for deciding if a task leads to an objective is:

Ask is the object produced by the task something that could stand on its own outside the project and in that sense valuable in its own right?

If the answer to the first is “Yes” then it is likely to be a task that leads to an objective. Please take care; this is just a “rule of thumb” so look for things as minor outcome that are real milestones to getting the project finished. It may be useful to think of the project as a pyramid where the final project outcome is at the top and below it are layers that have been generated progressively from objective minor outcomes so that we eventually get to the top.

The format for an objective is much the same as for an aim but with no target and two added features in that they must be progressive and bounded. There is only one aim but there may be from 3 to 6 objectives that show a progression that leads us to the overall project outcome.

Progressive – objectives must build sequentially so that collectively they amount to reaching the aim.

Activity – Ideally we look for a single activity that will generate a minor project outcome that can be expressed in a form that can appear in the project document

Spotlight – what is the data area focus of the objective's activity?

Outcome – In this element you say how the outcome of your objective will be expressed knowing that this must be in a form that can be written into the project document.

Bounded - objective outcomes must be achieved and available within the project period and must not refer to anything that might occur after the project document is completed and submitted

Example – To model and document the software development process.

Activity = model, **Spotlight** = software development process, **Outcome** = a document, Bounded – yes we can do this activity within the project period (in this case we cannot show progression as that only applies to the complete collection of objectives)

It is easy to become completely muddled with objectives and one source of this muddle is the distinction between a project objective: one about what a student can do and evidence in the project document and operational ones: those that have some real world effect that might happen after the project has been completed. In simple terms if you set an objective in your project it must be completed within the project's time scale. Let us just take an aim and look at some possible objectives.

Aim = To report on how the bicycle is an aid to mobility in a modern urban environment

Sample Objective 1 – “To list in a report the components of a modern bicycle”. This is fine since clearly it is something that you can do and evidence in a project document so somebody else could check what you have done.

Sample Objective 2 – “To describe how a bicycle functions”. This is no good since although it is clear that you can develop a description, no one can check it unless you write it down. Better to say “To describe by means of annotated diagrams how a bicycle functions”

Sample Objective 3 – “To understand how a bicycle helps urban workers”. This is no good because although you can do it no one else can check it. Better to say, “To prepare a report explaining how urban workers could be helped by the use of a bicycle”.

Sample Objective 4 - “To ensure that workers get to their office on time by using a bicycle”. This is no good because you cannot do it and if you cannot do it no one can check what you have done. It also sounds more like an aim than an objective because it hints at a target. Better to say “To report on bicycle usage strategies that might be applied by urban workers to ensure they get to work on time”.

Sample Objective 5 – “To implement a bicycle repair system”. This is no good since you can clearly do it but it cannot be checked in your project document. But you could say “Report on the implementation of a bicycle repair system” or “Produce a design document for the creation of a bicycle repair centre”.

Sample Objective 6 – “To ensure that bicycles conform to BS 7898”. This is not really much good as it is in essence a requirement and not something that one can do within a project itself. However, one might have written “To prepare a report showing how a bicycle can be evaluated for BS 7898 compliance”.

6.13 Words needing care in Aims, Objectives or Research Questions

The key thing is to look at the main verb (activity) you are using and ask ‘does it tell me what to do as a practice’, if not then its use is suspect. A good way to assess if the verb is strong enough is to connect it with an outcome. So we might write ‘Create a framework...’ – here we have the activity ‘create’ and the ‘outcome’ a ‘framework’ and it is easy to see that it can be done.

6.14 Writing a Title

The title is the name of your project – rather like the name of a novel, something that catches a potential reader’s attention but just gives a hint as to what the work is all about. Think of it as a kind of nickname or slogan for your project and as such it is not a good idea to try to use the same set of words for the title, Research Question and aim. Titles typically have two elements:

Aspect – this is the particular focused area of your study

Why – this says why it might be a useful aspect

Mentioning the means by which you solved your problem should only be included in the title if it is crucially important. As an example, suppose your project was concerned with the development of a database and you used Microsoft Access. Unless your project compared your product with a similar database implemented in Oracle, say, then the tool you used to solve the problem is not as important as the problem you set out to solve.

Be careful with titles, there is a tendency to use the title to say what you will do. The purpose of the title is to give a concise name to what you do. Avoid noise words or phrases such as: “A report into...” (redundant: of course it is a report!) or words like “study”, “investigation”, “enquiry” and “development” are often similarly just noise. It is also usually very unwise to express the title of your project as a question although a title in the form of a proposition is often quite useful as in example 1 below. Here are some examples of good titles:

Planar Similarity – A Possible Software Quality Measure
Heuristics in the Stages of Soft Systems Methodology
A Taxonomy of Heuristic Problem Solving

7. WORKBOOK 7 – BASIC RESEARCH METHODS CHECKLIST

In research we are usually trying to do one or more of the following: understand something, explore something, describe something, explain something, improve something, build something or prove something. To do any of the above, you will have to decide what data you want to collect and choose rationally a research method as your primary research vehicle and build a research design around it.

You need to exercise care here so as not to become confused between a Research Method, which is a framework or model for the whole research project, and Data Collection Protocols, which are vehicles for actually collecting the primary data and might include such things as interview, observation, questionnaire, seminar or role playing.

What follows is just a summary of the methods and further information can be found in the associate project notes and there are many books available on each of the methods listed below. There are many research methods but the list below presents the major ones.

7.1 Research Styles

This is a practical notion and you would be wise to think project ideas through in terms of these styles. There is no sense that one or other is superior and no reason why both should not be applied at the same time.

Quantitative – a style that represents information in numerical form. The numerical form might be graphs and statistics which can be used to show trends, comparison and similarities and the graphs might lead to equations which link variables or allow one to make generalisations.

The advantage of quantitative data is that there is solid evidence that can be permuted in a variety of ways to support or not support a contention. In general, one is counting the frequency of some event – say the number of times the user selects the wrong icon but, and it's a big but, the data is only truly valid in the context in which it was collected so one needs extreme care if we want to generalise.

Qualitative – is typically used to analyse how certain actions occur not just how often they occur. The information is usually represented in textual form of some kind as a description of some observable event or events. The usefulness of this is that it exposes the thought processes or reasoning behind a particular behaviour – why a user clicked the wrong icon. However, it does make the analysis and representation of the data more complex.

Although these are defined, in practice one does not usually start by thinking about the style and typically as you think about the problem and what primary data your research will collect to deal with it then it tends to define itself as predominantly quantitative or qualitative.

7.2 Research Approaches

There are two broad approaches to research, which is always essentially exploratory. In practice you do not decide the approach as such and it will effectively be decided for you when you formulate your research problem and construct your research design. However, we may loosely define:

Deductive – in the sense that we have a theory that we want to prove – in simple terms deduction amounts to a valid argument – that is if its premises are true then the conclusion automatically follows. Typically we form what is known as a null hypothesis. That is we set up our research question in the form that there is no effect of some parameter. For example, I might want to look at the significance of scripting languages on system development time. I could do this by setting up a null hypothesis that says 'I contend that the use of scripting languages have no effect on system development time'.

Inductive – in the sense that one hopes that the theory emerges from the data analysis as we go along. It follows that we don't have a hypothesis we just know that we want to explore a certain domain to see what emerges. For example, I might want to investigate the fact that students are not attending chat sessions but I have no idea why (I don't have a theory) so the whole point of doing the research is to explore the issue implied by the question and hope that something will emerge as I go along. So induction is a kind of grounded argument, the truth of whose individual premises would not *guarantee* the truth of its conclusion, yet one hopes that it would provide some evidence for it.

In short we might say that deduction is an outlook we take when we are sure that we know what the outcome is going to be but Induction is an outlook we take when we can only feel probable about a given outcome.

7.3 Research Outlook

Before we look at the various research methods it is useful just to records that there are two approaches that are available to a researchers.

Hypothesis Driven – this is the classical research paradigm where we have by some means devised a theory or speculation of some kind and the research is then directed at trying to show that the theory or speculation is valid. For example, we might theorise about who buys Gel Pens and then try to show that it is true, or more usefully try to explain in a report why it is true

Data Driven – it often happens that when we embark on research we don't have a hypothesis which we are setting out to test. This is very common today where corporations have vast databases and want to see if there is anything useful in there that might for example lead to competitive advantage. It follows, that in these cases we don't start with a hypothesis but we examine the data sets looking for patterns or outliers or indeed anything that might allows is to formulate a theory of some kind. For example, we might look through millions of sales transactions and then to hypothesise that people who buy Gel Pens all have beards and wear glasses. If this theory is true we can better target our Gel Pen products.

7.4 Which Method to Use?

There are many methods/models that we can use for setting up a research idea, the most common being: case studies, vignettes, action research, experiments, quasi-Experiments, surveys, biographies/histories, grounded theory, ethnography and requirements gathering. It is never easy to decide on a method or perhaps more than one method, but the following may help you to make up your mind. Start by asking what exactly are you trying to do or find out? This will help you decide whether you need a qualitative or quantitative approach. So here are something you might consider:

Choosing a method will depend on many factors such as: context, available literature base, basic research purpose, is the domain changing rapidly, time available, skill available, sampling and other practicalities, access, your personal stylistic inclinations, reason for the study, what kind of outcome you want, cost, quantitative/qualitative, scale, control, sensitivity of the data and so on. Notice these factors are almost all about practical things - the whole point being that a design has to be carried out and that means it has to be practical.

7.5 Research Basic Purpose

In research, usually we try to do one or more of the following: understand something, explore something, describe something, explain something, illustrate something, improve something, build something or prove something. It is therefore very important when you are trying to decide on a method to keep this basic purpose uppermost in your mind.

7.6 Rationale: Case Studies

The case study method focuses on just one, two or twenty examples – such as your place of work, or one element of your organization or several aspects of a problem area. Typically:

1. Case studies are commonly used to **illustrate** or **understand** a problem or **indicate** good practice.
2. Case studies always have a context so make sure you are aware of it.
3. Case studies are usually qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain or describe some activity or phenomena.
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. There are broadly speaking two ways to begin case studies. This first is that you can set criteria and then go looking for relevant cases or secondly you can design and create the cases.
7. For most case studies there is usually be a longitudinal element - that is the cases will run over a fixed time period and you will periodically visit each case to collect the data.
8. There are several kinds of case possible:

Unique – implying that the setting and context are extremely rare and there may no be another chance to study this problem area again.

Critical – implies an important theory that you want to test and a particular case fits that profile.

Representative – implies that the case profile represents a typical or everyday situation.

Revelatory – implies that the case profile allows a researcher to study a situation never before looked at in detail and its context may be come common.

9. In practice you can use the following to organise your cases but remember once you have your case design you will need permission from whoever is necessary.

How many cases – be practical because there are time limits.

Case Criteria - add as many criteria as you think necessary to pin down the data location but don't have so many that you will never find a case that fits.

Sample criteria (collection protocol) – add as many criteria as you need to pin down a particular sample point where a unit of data can be obtained.

Visit Frequency - each case must be visited to get the data so work this out by looking at how much total time is available for the study.

Data collection Vehicle – by observation, interview, document analysis, etc. You will have to have a protocol to say when a valid sample arrives.

7.7 Rationale: Vignettes

These are perhaps best thought of as micro case studies or snapshots that illustrate just one idea and almost always are qualitative in their application. Typically:

1. Vignettes are commonly used in research contexts where actions, motives and judgements are to be explored, often in sensitive situations and you want to extract and **describe** examples or **illustrations** of significant elements in that problem domain
2. Vignettes always have a context so make sure you are aware of it.
3. Vignettes are essentially qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain, test an idea or describe some activity or phenomena.
5. Typically you cannot control and indeed have no desire to control the events being looked at but the events should be contemporary.
6. Vignettes enable participants to define the situation in their own terms or for their needs.
7. Most vignettes are "one off" events and as such act as indicators of an idea rather than as some sort of proof of concept. Therefore, this may also be useful when only a small sample is possible.

7.8 Rationale: Action Research

The main purpose of action research is to improve identified practice in some way. Typically:

1. Action research is commonly used to conduct research at the workplace with a strong desire to **improving** aspects of your own or colleagues' work so
2. In this kind of research you must be in control of events and they must be contemporary.
3. Typically indicated as useful when the research question starts with 'how' and there is a desire to explain something and use that explanation to improve practice.
4. Because of its setting, it is obvious that the research design is linked closely to its context.
5. The whole point of doing action research is the research leads to change in practice.
6. The working strategy is: plan something, do something, observe the something and reflect on what has happened as a result of your actions.

7.9 Rationale: Experiments

This form of research is used where there is a hypothesis and an associated variable that you can control (the independent variable) that will produce a change in some other variable (the dependent variable). That is the whole idea implies that you can intervene by altering or controlling the independent variable. Typically:

1. Experiments are commonly used when you want to **prove** or at least **indicate** that something is true. In practice proof is very difficult as it would imply that your findings are true for everyone, everywhere and for all time and so then tendency is to say indicate rather than prove in most cases.
2. In very simple terms one forms two groups: one which is exposed to the intervention and one which is not and then we observe if there is any difference because of the intervention.
3. Typically indicated when the research question starts with 'how' or 'why'.
4. The researchers must be in control of the events being looked at and they must be contemporary.
5. The biggest risk is that there may be other variables involved which we are not aware of.
6. It is difficult to be sure that our sample is representative.

7.10 Rationale: Quasi-Experiments

This form of research is used where there is a hypothesis and associated variables but you cannot control any of them. It would be nice to think we always had time and resources to run a carefully designed experiment but unfortunately this is often not the case. In an experimental design one chooses the samples involved randomly and thus one has control. However, it may be that data already exists and you can test your theory on that existing data or it may be that you simply cannot get control over all the variables that you want. So an experiment and a quasi-experiment are very similar it's just that the quasi-experiment does not quite have all the trappings that a full experiment has.

7.11 Rationale: Surveys

This form of research is used when we want to ask a group of people a question or questions. Typically:

1. Surveys are commonly used when one needs to get and express an overall **understanding** of the properties in a given domain.
2. One could of course also survey 'things' as well as people.
3. Surveys lend themselves to future replication.
4. Typically indicated when the research question starts with 'who', 'what', 'where', 'how' many' and 'how much'
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. Questions must be well-designed and unbiased and may be asked by interview or questionnaire.
7. Be careful to distinguish questions that are asking for facts and questions that are asking for opinion
8. The results will be very dependant on having a big enough and representative sample.
9. Be clear as to how the data will be collected – by observation, interview, questionnaire, etc. You will have to have a protocol to say when a valid sample arrives.

7.12 Rationale: Biographies/History

This form of research is used when we want to trace an historical event and analyses/evaluate its history as this may lead to insights or explain certain action so that lessons may be learned.

1. Biographies/History are commonly used to form a **description** and **explanation** of events.
2. One can use this to look at individuals or organisations or even technology.
3. Typically indicated when the research question starts with 'what'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. Be clear as to how the data will be collected – by documentary study and interviews are common.
7. Histories are naturally chronological and are characterised by epiphanies (pivotal events) and almost always exists in a context.

7.13 Rationale: Grounded Theory

Here the main idea is to use research to arrive at a theory based (grounded) on collected data. Grounded theory is quite difficult to understand and practice.

1. Grounded theory is used in situation where the theory is unclear or even unknown and so there is a need to **explore** seeking **description** and **explanations** in a domain.
2. One can use this to look at organisations or technology.
3. Typically indicated when the research question starts with 'why'.
4. You cannot control the events being looked at but the events need not be contemporary.
5. This is typically a qualitative study.
6. Be clear as to how the data will be collected – by documentary study, interviews, questionnaires etc.
7. Grounded theory is systematic in that the idea is to gradually move closer to a position where we can suggest a theory or proposition.
8. The basic unit of research is the category which is something that may represent a unit of information and might be almost anything.
9. The essence of grounded theory is in its data processing where various forms of coding are used to gradually unlock meaning in the data.

Open Coding – essentially the formation of the initial categories of information – it is characterised by looking for properties or asking when the something is a dimension of the research space.

Axial Coding – this is about trying to assemble that data after open coding. This can be done by using a diagram or some logic that connects things or looking for causes or looking for contexts and consequences.

Selective Coding – here the researchers invents a plausible storyline that integrates the categories in the axial coding model.

Matrix – a final step (though often omitted) is to produce a conditional matrix that is supposed to make clear the social, historical, technological or economic conditions that prevail in a situation.

Theory – one hopes that as a result of all this processing a theory will emerge which of course may go on to be tested by a formal experiment.

7.14 Rationale: Ethnography

This form of research is used when to immerse ourselves in the day to day life of an organisation or group. In this context ethnography is a description and interpretation of a cultural or social group.

1. Ethnography is commonly used when we want a reflective **description** expressed in an **interpretive** manner.
2. One can use this to look at individuals but more typically organisations.
3. Typically indicated when the research question starts with 'why'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. You may alter the events being looked at because you are normally a participant observer.
7. Be clear as to how the data will be collected – by participant observation.
8. Ethnography is about immersion in a culture: behaviours, language, structures and functions.
9. In such studies one often encounters gatekeepers, key informants and communication relies on a sense of reciprocity by investigator and his subjects.

7.15 Rationale: Requirements Gathering

Requirements are simply a statement of a systems service (what it must do) or constraints (what it does not necessarily do). In practice saying what a system must do is often extended to how it will do it. This method is a form of action research but it differs in that the only contact one has with the people involved is at the requirements stage and possibly at the implementation stage though this may vary depending on the systems life cycle employed. You should use this method when you are setting out to build an application of some kind such as a computer application. There are 4 stages of requirements.

Functional Requirements - These are requirements that say what a system does or is expected to do. Typically this would involve or include most of the following: process descriptions, details of all inputs/outputs and details of all the data that must be held in the system.

Performance Requirements - This is usually understood to mean requirements that describe aspects of the system that are concerned with how well it provides the main functional requirements. For example: performance criteria such as response times or how long it takes to print a report, data throughput and storage needs and security considerations.

Technical Requirements - This aspect of requirement looks at the tools and method used to build the system. For example, it may happen that you have to use a certain database package or for other reasons you need to select a particular scripting language and so on. More often than not this aspect amounts to looking at technical constraints that must be applied in building the system.

Usability Requirements - Requirements that ensure that there is a good match between the system and its users. In most cases usability is expressed in terms of measurable objectives.

7.15.1 The Requirements Document

The system and software requirements are usually documented in a formal manner so that ones understanding may be communicated to customers and system builders. The requirement document describes the following:

Services and Function – that the final system must deliver.

Operational Constraints - under which the system must operate.

Development Constraints - on the process used to develop the system.

Properties of the system - in the sense that it may have unplanned additional functionality.

Links - definition of other systems with which the system must integrate.

Domain - Information about the application - for example how to carry out certain tasks.

Definitions – acronyms, abbreviations etc.

7.15.2 Stakeholders

These are people who will be affected by the system and therefore should have a direct or indirect influence on the system requirements.

7.15.3 A Process Model

As a process model we might define the requirement process as follows.

7.15.4 Requirement General Questions

There are perhaps four general questions we might ask when attempting to gather requirements

Problem - What are the problems with the current processes?

Improvements - What are the improvement goals?

Reference. Kotonya, G. and Sommerville, I, (1997), Requirement Engineering, Wiley, ISBN 0-471-97208-8. This book is useful because it also contains excellent reading and reference lists.

7.16 Research Design

Finally, you must set out your research design. That is, explain how you will get your data – and this must be done in great detail. In summary, then, your research design is the blueprint of your research project which enables you to deal, systematically, with:

What questions to study?

What data is relevant?

What data to collect – you will need to work very hard here so that you can rely on your data.

Are there any practical limitations to what you can do

How to analyse the results – don't shirk this.

How to decide in which contexts your findings are applicable or can be exploited.

The main purpose of your research design is to help you avoid a situation in which the evidence you eventually collect does not address your initial question.

7.17 Research Process Development

It is quite common is many kinds of research but notably in Case Study and Action Research for the researcher's perceptions to change as data emerges. Often this will imply that the research design has to be changed or amended if it is to remain meaningful. These changes may be small such as a slight modification to the Research Question or aim but occasionally it may be necessary to make significant changes. For this reason researchers must always be careful in their design to allow a little flexibility if they can to accommodate possible unforeseen circumstances.

8. WORKBOOK 8 - BIBLIOGRAPHIC REFERENCING HARVARD APA

This workbook is a short summary of the APA style guidelines as contained in The Publication Manual of the American Psychological Association, 5e, 2001 (Subject Reference Collection: 808.02 AME).

The APA style is based on the Harvard referencing system whereby the date of publication follows the author name(s), and in-text references refer to items in the reference list using the author surname and date of publication, in brackets.

Referencing is important in all academic work as it indicates to the reader the sources of your quotations and borrowed ideas. Failure to indicate your sources is tantamount to plagiarism (literary theft). The purpose of the referencing system is to describe your sources in an accurate and consistent manner and to indicate within the text of your paper where particular sources were used.

Please note that there are two sections to this document:

How to **reference** correctly a source in the **bibliographic** section of your work

How to **cite** correctly a source in the **written** part of your work

Don't Get Caught Out! If you do not reference correctly you may lose marks or your work may be returned unmarked to you for correction. Therefore:

Keep a careful note of all sources used as you prepare your assignments.

Record all the details you need about a library book (including page numbers for any quotations) **before** you return it - someone else may have the book if you try to go back and check later.

Make sure you write down the source details you need on any photocopies or downloads you make.

Remember to print or save details of any website you want to refer to and record the date when you accessed the information.

8.1 Reference list (Bibliography) at end of Project/Dissertation

The reference list should be arranged alphabetically by author surname. The APA format requires book and journal titles etc. to be italicised, although we are not strict about that.

As a rule in projects and dissertations it is normal to produce two lists. The first is a reference list and that **MUST** only include sources you have cited. The second is a bibliographic list which includes all other sources you might have found but did not cite – this list is to allow the reader to explore the topic further if they wish.

8.2 Books

The details needed for a book can normally be found on the front and back of the title page. Make sure you locate the name of the publisher rather than the printer or typesetter. You need the name of the publisher in your reference list. Ignore any reprint dates; you need the date when the first, second, third edition etc. of the book was published according to which edition of the book you are using.

8.3 Journal articles

The details needed for a journal article can usually be found on the contents list, front cover or article itself.

8.4 Printed publications: Examples of References

The following are sample if how to correctly reference a source.

Book – pattern: Author, Initials. (year). Title of book. Place of publication: Publisher.

American Psychological Association. (1994). Publication manual of the American Psychological Association 4e. Washington, D.C.: Author.

Encyclopedia of psychology. (1976). London: Routledge.

Gardner, H. (1973). The arts and human development. New York: Wiley.

Moore, M. H., Estrich, S., McGillis, D., & Spelman, W. (1984). *Dangerous offenders: the elusive target of justice*. Cambridge: Harvard University Press.

Strunk, W., & White, E. B. (1979). *The elements of style* (3rd ed.). New York: Macmillan.

Note: Only list up to 6 authors. The 7th and subsequent authors are abbreviated to et al.

Edited book

Maher, B. A. (Ed.). (1964-1972). *Progress in experimental personality research* (6 vols.). New York: Academic Press

Article in edited book (Chapter) - The basic pattern for a reference to a chapter in an edited book (where the chapters have been written by several different people) is:

Author of chapter, Initials. (year). Title of chapter. In Initials. Name of Editor/s (Ed.) *Title of book* (pp.start and end page numbers of chapter). Place of publication: Publisher.

Vygotsky, L. S. (1991). Genesis of the higher mental functions. In P. Light, S. Sheldon, & M. Woodhead (Eds.), *Learning to think* (pp. 32-41). London: Routledge.

Encyclopedia entry - If the entry has no author, begin the reference with the entry title followed by the date of publication.

Lijphart, A. (1995). Electoral systems. In *The encyclopaedia of democracy* (Vol. 2, pp. 412-422). London: Routledge.

Government publication

Great Britain. Command Papers. (1991). *Health of the nation* (Cm 1523). London: HMSO.
Great Britain. Home Office. (1994). *Prisons policy for England and Wales*. London: HMSO.

Report

Birney, A. J., & Hall, M. M. (1981). *Early identification of children with written language difficulties* (Report No. 81-502). Washington DC: National Educational Association.

Conference paper in published proceedings

Borgman, C. L., Bower, J., & Krieger, D. (1989). From hands-on science to hands-on information retrieval. In J. Katzer, & G. B. Newby (Eds.), *Proceedings of the 52nd ASIS annual meeting: Vol. 26. Managing information and technology* (pp. 96-100). Medford, NJ: Learned Information.

Journal article - The basic pattern for a reference to a journal article is:

Author, Initials. (year) Title of article. *Title of journal*, Volume number - if there is one (Issue number), start and end page numbers of article.

Noguchi, T., Kitawaki, J., Tamura, T., Kim, T., Kanno, H., Yamamoto, T., et al. H. (1993). Relationship between aromatase activity and steroid receptor levels in ovarian tumors from postmenopausal women. *Journal of Steroid Biochemistry and Molecular Biology*, 44(4-6), 657-660.

Popper, S. E., & McCloskey, K. (1993). Individual differences and subgroups within populations: the shopping bag approach. *Aviation Space and Environmental Medicine*, 64(1), 74-77.

Weekly magazine article

Barrett, L. (2001, August 23). Daewoo's drive to survive in the UK. *Marketing Week*, 22-23.

Newspaper article

Caffeine linked to mental illness. (1991, July 13). *New York Times*, pp. B13, B15.
Young, H. (1996, July 25). Battle of snakes and ladders. *The Guardian*, p. 15.

Two or more works by the same author(s) with the same publication date - Where an author (or particular group of authors) has more than one work in a particular year, list them in title order and follow the date with a lower case letter a, b, c, ... For example:

Harding, S. (1986a). The instability of the analytical categories of feminist theory. *Signs*, 11(4), 645-64.
Harding, S. (1986b). *The science question in feminism*. Ithaca: Cornell University Press.

Anonymous works - If a work is signed "Anonymous", your reference must begin with the word Anonymous, followed by date etc. as normal. If no author is shown, put the title in the normal author position.

Note on source page numbers - Use pp. for page range only for encyclopedia entries, multi-page newspaper articles and chapters or articles in edited books. For articles in journals or magazines use the numbers alone.

Interviews and email messages - Because interviews and email messages are not considered recoverable data, you do not give details in your reference list. You should, however, cite an interview or email message within the body of your text as a personal communication: ...and this point was conceded (J. Bloggs, personal communication, August 22, 2001)

Legal References - Because the situation regarding legal references is complex and only US law is covered in the APA Manual, legal references will be covered in a separate guide.

Audiovisual sources: examples of references - Such sources are often complex but please note.

Films - The basic pattern for a reference to a film is:

Name of primary contributor - the director or producer, or both, Initials. (Role of primary contributor). (year). *Title of film* [Motion picture]. Country of origin - where the film was primarily made and released: Name of studio.

Reed, C. (Director). (1949). *The Third Man* [Motion picture]. United Kingdom: British Lion/London Films.

Spielberg, S. (Director). (1993). *Jurassic Park* [Motion picture]. United States: Universal Pictures/Amblin Entertainment.

If the film doesn't appear on the Library Catalogue, the Internet Movie Database <http://uk.imdb.com/> is a good place to check all the details needed for a film reference (follow the Company credits link to find details about the film studio/s involved). Alternatively, check Halliwell's Film and Video Guide.

Review of a film - If the review is untitled, put everything in square brackets in the normal title position and keep the square brackets.

Kinder, M. (2002). Moulin Rouge [Review of the motion picture *Moulin Rouge*]. *Film Quarterly*, 55(3), 52-59.

Malausa, V. (2001). Beauté du mensonge [Review of the motion picture *The Tailor of Panama*]. *Cahiers du Cinéma*, 558, 82-83.

Television programmes

Collinson-Jones, C. (Producer), & Dobson, E. (Director). (2003, July 14). Casualties of peace [Television broadcast]. London: Channel 4.

Single episode from a television series

This example shows the most complete information possible for a television episode. If details of the writer are unavailable, begin your reference with the name of the director.

Fraser, R. (Writer), & Geoghegan, S. (Director). (2003). Eyes wide open [Television series episode]. In P. Goodman (Producer), *Holby City*. London: BBC1.

Radio programmes

Portenier, G. (Producer). (2003, July 17). *Crossing continents*. London: BBC Radio 4.

Electronic sources: examples of references - The details shown below have been compiled according to the guidelines available on the APA Website (<http://www.apastyle.org>) in August/September 2001 (re-checked July 2003). Check this Website and the 5th edition of *The Publication Manual of the American Psychological Association* which is available in the Frewen Library for further guidance.

The basic pattern for a reference to an electronic source is:

Author, Initials. (year). *Title*. Retrieved month, day, year, from Internet address.
Banks, I. (n.d.). *The NHS Direct healthcare guide*. Retrieved August 29, 2001, from <http://www.healthcareguide.nhsdirect.nhs.uk/>

If no date is shown on the document, use n.d.

If the author is not given, begin your reference with the title of the document.

If a document is part of a large site such as that for a university or government department, give the name of the parent organisation and the relevant department before the Web address:

Alexander, J., & Tate, M. A. (2001). *Evaluating web resources*. Retrieved August 21, 2001, from Widener University, Wolfgram Memorial Library Web site: <http://www2.widener.edu/Wolfgram-Memorial-Library/webevaluation/webeval.htm>

Deciding your future. (2000). Retrieved September 5, 2001, from University of Portsmouth, Careers Service Web site: <http://www.port.ac.uk/departments/careers/plancareer/deciding-your-future.htm>

Electronic journal articles which are duplicates of the printed version - Use the same reference format as for a printed journal article but add "Electronic version" in square brackets after the article title:

Lussier, R. N., & Pfeifer, S. (2001). A crossnational prediction model for business success [Electronic version]. *Journal of Common Market Studies*, 39(3), 228-239.

If you are referencing an online article where the format differs from the printed version or which includes additional data or commentaries, you should add the date you retrieved the document and the Web address (URL).

Articles in Internet-only journals

Korda, L. (2001, July). The making of a translator. *Translation Journal*, 5(3). Retrieved August 21, 2001 from <http://accurapid.com/journal/17prof.htm>

Use the complete publication date shown on the article.

Note that page numbers are not given.

Whenever possible, the URL you give should link directly to the article itself.

Break a URL that goes onto another line after a slash or before a full-stop. Do not insert a hyphen at the break.

Articles retrieved from a database - Use the format appropriate to the type of work retrieved and add a retrieval date, plus the name of the database:

McVeigh, T. (2000, July 9). How your gestures can do the talking. *The Observer*, p.7. Retrieved September 10, 2001, from The Guardian and The Observer on CD-ROM database.

8.5 Citing references in the text

There are basically two forms. The first is when the author's name is naturally part of the sentence and the second when it is just a reference. References are made from the text of the paper to the full details of the work in the reference list in the following manner:

It is a contention of the paper, and this contention is supported by Williams (1995, p.45) who compared personality disorders ...

When an author, or group of authors, has more than one publication in the same year a lower case letter is added to the date. For example:

In two recent works Harding (1986a, p.80; 1986b, p.138) has suggested that ...

With two authors both names should be listed in each citation e.g. Duncan & Goddard, (2003, p.99)

With three to five authors name all authors the first time, then use et al. (and others). For example: the first time it would be Moore, Estrich, McGillis & Spelman (1984, p.33) and subsequent references to the same publication would use Moore et al.

For six or more authors, use et al. after the first author in all occurrences.

Note that when the in-text reference occurs naturally within the sentence "and" should be used before the final author.

When a source has no author, cite the first two or three words of the title followed by the year. For example:

... in the recent book (*Encyclopaedia of psychology*, 1991, p.62) ...

... in this article ("Individual differences," 1993, p.12) ...

Web pages where no author is given

However, if the author is designated as "Anonymous", cite the word Anonymous in your text e.g. (Anonymous, 1993, p.116).

When using quotations in your text

Try to observe the following methods.

Gardner (1973, p41) stated that, "The relative importance of the systems may nevertheless remain in approximately the same proportion"

Smith (1991, p84) found that "...there is no evidence that chimpanzees can produce a drawing and discern the object represented in it..."

Occasionally, very occasionally you may need to cite a work that you discovered in another work because you cannot find the source then observe the following examples:

Smith (1970, p.27) cites Brown (1967) as finding ...

Brown (1967), cited by Smith (1970, p.27), found ...

It was found (Brown, 1967, cited by Smith, 1970, p.27) that ...

If you need to use this form your tutors must approve it and you must show that you have made every effort to track down the primary source.

9. WORKBOOK 9 – WRITING UP A RESEARCH PROJECT

This document is in several sections covering everything from project supervision to grading.

9.1 Your and Your Supervisor

The student supervisor relationship is very important if a high quality project is to be the outcome. As a rule the supervisor will be interested in the topic area and will want to be active in its development although you as a student must do the work. However, your supervisor will not be expert in everything but will usually have some knowledge of simple statistics and the four main research methods: experiments, action research, surveys, case studies and application development.

9.1.1 Student Expectations

The normal expectation is that students have of their supervisor are as follows:

- Only be available for consultation for a limited time.
- Only supervise what the student does and not do the work for them.
- Advise on research design, scheduling and literature surveys.
- Advise on theoretical, conceptual and methodological issues.
- Advise on development of research skills.
- Advise on data collection, processing and analysis.
- Advise on ethical issues if they are relevant.
- Read, evaluate and be constructively critical of student work if given sufficient time.
- Have a good knowledge of the general area you are working in.
- Be in contact with the student regularly.
- Arrange if necessary supervision chat sessions.

For project students on distance learning programmes it will be possible to have meetings in the WebCT chat room, using IM or Skype where a full and detailed interaction can take place. These must be agreed with your supervisor and must be planned not to clash with other classes. However, some tutor may allow student to contact them any time they are seen to be online.

9.1.2 Departmental Expectations

Supervisors take a formal role and certain attitudes and actions are expected. In general they will:

- Visit the discussion board and email regularly within WebCT (at least 3 times per week).
- Set a mail forwarding address to their personal accounts in WebCT email settings.
- Devote at least 6 hours to the supervision process spread over the project duration.
- Conduct one-to-one chats as required with project students.
- Conduct student/supervisor communication within WebCT or their personal email account.
- Respond to a student query within a certain time frame (normally no longer than 3 days).
- Be familiar with all the project guidance notes and workbooks.
- Be familiar with the project chapter profiles.
- Make sure students know if they are to be away for an extended period.
- Be aware that students may make contact through any one of their three WebCT accounts.

The essence of online supervision adequacy is based on the quality of communication between supervisor and student with the intent that we want the learning experiences to be exiting, stimulating and self-rewarding. In practice this means that communication must be frequent, lucid, critical and yet encouraging.

Supervisors should be aware that if they set email forwarding in WebCT they will effectively get an automatic alert when there is mail for them. If the student has also set mail forwarding then supervisors will be able to reply immediately otherwise they will have to go into WebCT. However, there is no alerting mechanism if a student posts a question into discussion so supervisors must visit the site from time to time so as not to miss any messages.

9.1.3 Supervisor Work Reviews

Supervisors will read your written work. However, when they do this certain rules apply:

Finished work – you should supply your supervisor with written work as it is produced chapter by chapter but it must be finished work. In this context finished work means that the format and content are the very best you can produce and in accordance to the guidelines found in this workbook. The tutor's role is not to act as some kind of filter for rough work or polishing multiple drafts which you want to improve in effect making them do the work for you. If a tutor suspects that the section you have sent in is not in its final form they will return it to you without comment.

Action on Feedback – if you are given feedback on any part of your work then you are expected to study it with care and commitment. However, it is up to you how to respond or even ignore what you are told but in all cases the consequences that follow are entirely your own responsibility.

Responding to Feedback – in all cases you are expected to respond to feedback. This may take several forms: writing to your supervisor saying that you don't agree with him or perhaps offering further explanation or as in most cases making changes to the content or structure of your project document. When you make document changes in response to feedback they are to be shown **shaded** so your supervisor can easily see exactly what you have added or amended.

Questions to Tutor - your tutor will not answer any questions regarding whether your work is right, wrong, is it a pass, what mark will I get or is it good enough. The only thing you can expect in this area is that you tutor may advise you that the work is not ready for submission to the university. If this happens it will be entirely your own decision whether to submit or not.

Response from Tutor - in most cases your supervisor will only suggest that you do something or ask a question designed to point you in a new direction. Normally, the tutor will not supply you with any project content since that must be provided entirely by you. The reason is that the work is yours not the supervisors.

Preparation - Your supervisor will expect you to be familiar with all the notes and workbooks contents. You should therefore be careful that you don't waste supervision time asking questions to which you already have the answers.

9.1.4 Chat Session

Chat sessions for project students will usually be one-to-one and are typically used when there are particularly awkward difficulties – chat will NOT be the norm during projects and your tutor will have no expectation that chat will be used.

9.2 Overview of Project Structure

Here are some general guidance notes – they are NOT suggested chapters but general content guidance on the project as a whole and have a sharp process focus.

9.2.1 Introduction summary

This is about the problem theme and its setting, client context, topic area, personal theory, Research Question or application functional description and intended project outcome, general research orientation followed by a well-defined aim and sound set of objectives. The introduction is to be precise, concise taking a discussion form that is explanatory and focused on giving readers a clear, coherent and comprehensive view of what the project is about.

9.2.2 Preparation for Research

This is your study of the topic area and research methods that you will need to know about. You will have to justify and explain the methods you intend to use; it is also your study of other people's work in the area that you wish to investigate - and a description of how you learned from their research.

Literature Review - What has been done before in this area - related to a particular problem theme and Research Question. This is all about preparing one's mind with all the topic area and research knowledge you will need.

Research Review - research into how the project investigation could be done and supported. At this stage student will already have an outline plan based on their approved specification but now the whole design must be thoroughly reviewed before actual work begins.

Knowledge of Alternatives – build a simple decision base which allows one to consider which methods could be used and how could they be used for this project.

Choices Made - which methods are to be used and rationally consider why they are good enough for the purpose.

9.2.3 Core Research

Here you execute the refined research design translated into a practical plan to obtain the collection of primary data and process it using acceptable methods into the intended project outcome.

9.2.4 Evaluation and Conclusions

This is the stage that looks at how one finishes off a project by a process of evaluation and the drawing of conclusions. In particular, it is needful to look at how one evaluates what was done and how it was done – that one needs to consider the project product (or outcome) and the project practice. For our purposes evaluating will be taken to mean reflecting on product and practice.

Many students confuse evaluation and conclusions but for a full consideration of the research work one must look at all project specific results and outcomes as well as practices and evaluate them and then perform the more difficult step of drawing generalised conclusion about both product and practice.

Evaluation of Project Product – the project outcome or product is normally evaluated against objectives, other existing products, using defined criteria or some form of expert evaluation. Additionally, one needs to be aware of any constraints that might have an impact on the applicability of the outcome

Evaluation of Project Practice - evaluation of project practice is more difficult than evaluation of project product and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way'. Additionally, one needs to be aware of any constraints involved, including time management that might have impacted on the use of best possible practices.

Conclusions - need to be considered thoughtfully as this is the point where one looks for implications and meaning that arise out of an attempt to generalise the findings.

9.3 Writing up your Project

The following sections describe elements that occur in almost all projects and which are generally important in constructing scholarly work. Do not be tempted to ignore these instructions – anyone who departs from the spirit of them may have their work returned for correction prior to formal marking.

9.3.1 Main Project Body Page Layout

The following example shows how each page of a project report should look, note that each chapter should start on a new page and that it is NOT necessary to actually say Chapter 1, Chapter 2 and so on as it is the heading that is important. Do not use numbering to greater than to three levels but you may use indented (but not bulleted ones) entries within a section at any level.

1. QUALITY CONTROL IN PROGRAM DEVELOPMENT

In this chapter the nature of quality will be discussed and its relation to physical measurable properties that might characterise quality.

1.1 INTRODUCTION

This project discusses a possible strategy for devising a program development methodology that goes some way to guaranteeing the qualities of the delivered system. In particular it will concentrate on just two aspects - that of developing generic designs and code and how such designs could be assessed for quality and function. The strategy is based on the simple premise as endorsed by leading authors in the field such as Blenkinsop, Wilson and Bowers that categories of problem can be identified and formalised. It is the contention of this report that such a process would more or less automatically:

Reduce - the complexity of the design process itself.

Ensure - the quality of the final product by:

Giving managers more control over the product development cycle.

Giving users more idea of the kind of system they are likely to get and much more say in what the shape of the product will finally be.

Releasing programmers from the drudgery of having to design the same piece of code over and over again, thus enabling them to concentrate their efforts on new

Formatting Note – you are encouraged to use these two forms of indenting: one with a heading in bold and one without as a means of structuring and indented section. The use of bulleted indents is not recommended anywhere in a project document.

1.2. Multiplicity of Design Factors

Every programmer has had the difficult experience of having to read and understand programs written by someone other than himself or herself. The sort of problem encountered may be aptly expressed in the following lines.

Everything has been thought of before, but the problem is to think of it again. (Goethe)

Many other authors, notably Frewin (1989) have discussed the notion of 'quality model ratios' and in essence this idea means that software systems have an implied model which can be accessed for

1.2.1 Multi-Tier Systems

In modern client sever systems

1.2.2 Interface Facades

In this case we look closely at the Internetetc

9.3.2 Plagiarism Checking

A software tool will check all your sources automatically and if plagiarism is suggested it will be dealt with very seriously since the reputation of the whole course and of the University is at stake. You must remember, that copying, paraphrasing, summarising and similar techniques where the material is extracted from a source must be properly acknowledged.

A simple rule is that if you use more than 6 consecutive words from a source it must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

9.3.3 Writing Abstracts and Identifying Keywords

The function of an abstract is to summarise your project, its context and its conclusions in order to give the reader an overview of the main project theme so that they can make an informed decision on whether they want to read the entire report. A good basic structure might be defined as follows but it will usually be limited to around 300 words.

What was the project about?

What did you actually do?

What were the conclusions?

It is normal to add keywords or phrases after the abstract to act as specific pointers to content. There are no particular rules about how to construct these words or indeed how many there should be but typically there are 5 or 6 and to be useful they must be chosen with care in the sense that they might in themselves be regarded as a sort of abstract of ones work.

9.3.4 Standard Appendices

Project reports MUST include the following appendices:

Your Project specification – it may be brought up to date from that submitted at the start

Your project plan expressed in an appropriate format

A glossary if this is appropriate

A full reference list of work that you cited

A bibliography (may be combined with your citation list)

Each Appendix should be introduced by a title where the number (12 in this case) should follow on from the numbering within the body of the report: **12. Appendix A – Project Specification.**

9.3.5 Typical Project Organisation

Below is a suggested organisation for your complete project.

Briefing Pages

Heading pages (examples follow later in the section)

Plagiarism declaration

Abstract for Report including keywords

Acknowledgements

Dedications

Content list (automatically generated) for all headings, tables and figures/graphs etc

Introduction:

Brief topic area outline and background to problem
Presenting Problem definition
Real World Target relevant to the problem
Speculation of problem causes and possible solution routes
Personal Theory on the best solution route
Research Question/Application Description
Discussion of expected project outcome
Scope of work
Aim & Objectives

Literature Research (see Workbook 5 for recommendation for various project styles)
Detailed consideration of elements that help you focus on your topic area

Research Design

Research Method and its rationale in dealing with the research question/application
Process to collect Primary Data
Processing of the Primary Data to get an outcome

Application Testing (Engineering project only)

Design of Tests
Test Results and conclusions to be drawn from testing.
Implementation plans

Results Discussion and Presentation (study projects only)

Discussion and presentation of results
Generation of intended project outcome

Evaluation (these are specific to what you did)

Detailed evaluation of what was actually done – your practice
Detailed evaluation of your project product/outcome including objectives not met
Met/Not met objectives

Conclusions (here one tries to generalise what was done)

Generalisations based on a consideration of both product and practice
It is also possible to examine the following minor conclusion elements

- Usefulness of literature sources
- Future work/development
- Relevant aspect of the course used during the project period
- Changes one would make if project were repeated
- What you have learned
- Value-added features

References and bibliography (see workbook 5)**Content of Appendices**

The following items must be in a set of Appendices. These may be bound separately if the composite document becomes too large (more than 100 pages).

- Code listings
- Project Specification and project schedule
- Inclusions (copies of relevant documents such as policies, invoice layouts, diagrams etc)
- Questionnaires.
- Summary interview transcripts
- Details test plans
- Requirement catalogues
- Glossary
- Other

9.3.6 Project Types Sample Outline Contents

Broadly speaking there are two kinds of project: engineering where you build an application of some kind and study based where one would investigate in depth some idea. Here are some sample contents lists that show chapter or section headings for the different project styles. However, if it is obvious that these samples have just been copied into your project with minor changes then your work will be rejected. See Workbook 9 section 9.3.5 for further general details.

Sample Study Style Report Contents	Sample Engineering Report Contents
Title: Internet Marketing – A Users View	Title: BrokerBase – Insurance Sellers Information System
Chapter 1. Introduction to Internet Marketing	Chapter 1. Introduction to System
Introduction and contextualisation IT marketing problem theme Problem Theme and target Speculation and Personal Theory Discussion and Exploration of Research Question Project aim and objectives	Introduction and Situation Overview Situation based Presenting Problem Application background and context Application overview Project aim and objectives
Chapter 2. Literature Review	Chapter 2. Literature Review and Application Scenario
Introduction to Internet Marketing Marketing Planning eCommerce Technologies and Tools Costs and Benefit Estimation Consumer Orientation and Market led operations IT supported Marketing and selling techniques Product, Price, Place, Promotion and Customer expectation IT supported Experiential marketing Security protocols and languages Auditing and secure payment systems	Outline of Insurance Brokerage practice Background Review of the Application Scenario Outline of Application Build Process and Tools
Chapter 3. Research Design	Chapter 3. Requirements Specification
Research Method Selection and Rationale Primary data collection process Data specification Data locations and expectations Collection Protocol Processing of Primary Data Collection Outline Results Project Outcome	Outline of the requirements (requirement catalogue into appendix) Research Plan for requirement gathering: functional, performance, technical and usability Outline Requirements catalogue Analysis and Evaluation of requirements
Chapter 4. Evaluation (Project Specific)	Chapter 4. System or Application Design
Evaluation of Project Outcome Evaluation of Research Methods and Protocols used	Principles used for this design Overall system design Build Process Overview Database design Component design Interface design including website
Chapter 5. Conclusions (Project Generalisations)	Chapter 5. System Implementation and Testing
Generalisations on the research Outcome Reflections on what was learned etc	Testing strategy Testing plans (detailed plan placed in appendices) Test results (detailed report placed in appendices) Application Implementation plans
	Chapter 6. Evaluation
	Evaluation of the application Evaluation of practice (methods and tools used)
	Chapter 7. Conclusions
	Generalisations based on the Application Reflections on what was learned Future work Etc
Notes	
1. Whatever the project styles the appendix must include: the project specification, glossaries, references lists, bibliographies. The appendices may be attached to the main report or they may be placed in a separate document.	
2. Remember these are just samples and you may well have different numbers of chapters and different heading and sub-headings	
Table 6. Sample Project Content Outlines	

9.4 Report Writing

In your research you will often have to write reports and of course you will have your final report to write. Reports are a special form of writing and therefore you need to note that reports are:

- Written for defined purpose.
- Written and targeted at specific audience.
- Written systematically to present your findings.
- Focused on what you have done.
- Information structured and formatted to lead reader quickly to main themes and findings

9.4.1 Structural Elements

The following tables are intended to give you some guidance on how to construct report in a scholarly fashion and in a way that leads to clear and concise presentation. It is important to structure all your work in a way that enhances its usefulness and utility. The following is a list of all the major structural elements, though there is no need to use all of them in every document you produce. The best advice is to choose a structure and then those elements that best suit the work in hand.

Structure	Description	Location
Title	A focused and short description of the document that summarises the deliverable element	Front page and above the contents list
Contents List	A short index based on the major chapters and/or sections	Before the main document begins but after the title page
Glossary	Used to list and describe special terms or abbreviations	Towards the end of the main document
Index	A detailed listing of all important words or phrases specifying location in main text	After the glossary if it exists otherwise after the main document
Appendix	For inclusion of explanatory notes, special documents or copies of originals	After the glossary but before the index
Footnotes	Notes at the bottom of pages and linked to pieces of text.	Immediately before the page footers
Headers	Standard text	Every page
Footers	Standard text	Every page
Keywords	Words or phrases used to form a simple classification of your work	Near front of report
References	List of all reference material in an approved manner	Toward end of document

Table 7. Main Document Physical Structural Entities

Organisation	Description
Chapters	Major elements in the development of the subject matter of the document
Sections	Minor elements in development of each chapter
Headings	Major Information Content indicators
Indents	Used to emphasise small but important points in the text
Bullets	Used to further emphasise an indented text
Tables	Used to represent important information concisely
Paragraph numbers	Used when it is necessary to reference all parts of a text
Page numbers	Used for indexing purposes
Diagrams	Used to show idea or data pictorially
Captions/Legends	Added to diagrams where necessary
Columns	Use when the subject material lends itself to such a view

Table 8. Main Document Structural Devices

Presentation	Description	Examples
Font	Letter style and size	May be proportional or fixed point
Renditions	Printed form of font	Bold, underline, italic, reversed
Orientation	Page format	Portrait or landscape
Form	Delivery form	Paper, electronic
Table 9. Main Document Structural Properties		

9.4.2 Report Writing Stages

There are a number of stages to writing a report and they require you to be focused on what you are trying to show as the core of your report.

What are your trying to show – this really goes along with the underlying purpose of your research question – typically this will be about wanting: to inform, to explain, to evaluate, to prove, to advise, to recommend, to predict or to bring about changes.

Collect and sift material – it is important to jot down ideas relevant to your purpose. These jottings will help you form an action plan for gathering information from other documents, visits, interviews, observation, surveys etc.

Note - information sources as you find them

Organise and structure the material - group your work into chapters, sections and sub sections. Make sure the order is logical.

Draft and edit/redraft – to get a good report you may well have to re-write it several times and this may include complete re-ordering. It is important that you need to be concise and use a formal language but it must be clear and concise. Use simple, straightforward words and sentence construction and make sure your spelling and grammar are faultless. Use clear headings and sub headings with bulleted indentations.

Thematic – make sure your work has clear themes that are easy to follow.

Plain English - do not try to be over-clever or fall into jargon.

Read Saunders chapter 13 pages 414 to 443. Don't skimp on this or I might skimp when I mark inferior work!

9.5 Summary and Advice

Your final project must have a strategic dimension. This does not mean you can't build some software but if you do it will be in support of a strategic objective. So whatever you decide to do consider:

Why it is being done but note it will not be sufficient to just say why, you will have to show evidence for your conclusion.

Cost/benefit is a useful idea but in most cases it is very hard to show benefits. In any case you need to look at other possible ways of showing that something is worth doing.

Don't forget life cycle logistics - that is what are the costs per hour (for example) of running a system for say a 10-year life.

Also look for impact for what you do. For example something might be cost effective but may have a negative affect on some business element.

Think through your ideas; don't be narrow - question everything.

Traditionally strategies are developed around two themes: needs - what are the business needs (at a high level) and what are the business values (what does it regard as important)

9.6 Project Submission Regulations

Successful project reports may lodged in the University library, it is therefore important that reports follow a standard binding format as described below. Project reports that deviate from these regulations may be penalised and returned to you for correction and in extreme cases, failed.

Submission - two full bound A4 portrait orientation copies of your report must be submitted by the defined dates. The report may NOT be submitted electronically – the copies must be sent by courier to reach us by the defined dates. However, you must also submit soft copies on either floppy disc or CD/DVD.

Presentation and Submission Checklist – your project report submitted using the correct form shown in Workbook 10. The form must be bound into your project.

Report Length - the maximum permitted report length is 15,000 words, which usually translates into around 50 to 100 pages (excluding appendices). If your report is likely to be significantly longer than this, consult your supervisor as to what to include and what to exclude. You are warned that should you exceed the permitted maximum length the University may return your work unmarked.

Binding - the project and any separate appendices should be securely bound using tape or book binding - if that is not available then plastic ring binding may be used. No other form of binding is permitted. Binding covers should be a card of weight of 140 gsm and the normal colour is to be RED but any other colour may used in case of sourcing difficulties

Front Covers Format - the front cover appropriately spaced vertically should conform to the pattern shown below using 24-point Arial Narrow with centred text and bold as shown. Do not include the square brackets when you complete these formats as they are just placeholders

University of Portsmouth

Technology Extended Campus

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[HEMIS No.]

Supervisor: [Name of supervisor]

Project unit Code [Project unit code]
[Month and Year, e.g. September 2004]

Title Page - the first project contents page, appropriately space vertically must contain the following information in the order shown below using 12 point Arial Narrow/Time Roman type throughout. Do not include the square brackets when you complete these formats as they are just placeholders.

University of Portsmouth

Technology Extended Campus

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[HEMIS No.]

Supervisor: [*Name of supervisor*]

Project unit: [*Project unit code*]

[Month and Year, e.g. September 2001]

Abstract - [The abstract of the project should be between 150 and 300 words in length and constructed to say what the project was about, what you did and what were the conclusions]

Keyword List - [List of appropriate key words]

Acknowledgements Page - it is common practice to add a page listing those you wish to thank for their help and assistance. As a rule acknowledgements should **only** be given to people who helped you directly with your work but were not involved in it. For example, if a colleague supplied you with a statistical analysis they should be acknowledged. However, it is not usual, necessary or desirable to acknowledge your parents, your friends or your supervisor.

Submission Form and Plagiarism Declaration

You must add the following two pages which require a signature. In practice one adds the signature to the final bound copies.

Declaration of presentation Standards

Include at this point a completed copy of the project submission page shown in workbook 10. Be warned, that if you tick this page and the relevant element is not found to be present, the work will be returned to you unmarked for correction.

Plagiarism Declaration

I confirm that the enclosed written work (including application code) is entirely my own except where explicitly stated otherwise. I declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions. I understand that wherever 6 or more consecutive words are extracted from a source they must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

Include as appropriate

9.7 General Grade Criteria

Workbook 14 gives general guidance as to how projects will be assessed. Workbook 14 also contains a table of the criteria used, although the emphasis given to various aspects may vary depending upon the nature of the work and should be explained to students in assessment specific criteria.

9.8 Project Examination Board Reflections

This is a discussion based on observations made on the marking forms and in the Examination Board regarding the quality of the submitted document as final Master's projects/dissertations. Most of these faults are due to shallow and sometimes very shallow thinking on the part of the project student and that is unacceptable at Master's level. The following points are to help both supervisors and students avoid known pitfalls and so produce a project document to a high standard.

9.8.1 Project Introduction – Study Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem definition – common deficiencies were no discussion or poor discussion of what problem was being addressed by the project. Without such a discussion it is almost impossible for a reader to get any grasp of what the project is about. In projects we want to see just ONE major problem theme not several so it often requires clear thinking to set it at the right level. (See workbook 6 section 6.2 and 6.5)

Target and Outcome – there is often considerable confusion over these two ideas. The target is about what might happen in the real world based on the project outcome but often students cannot distinguish what the project will generate and what might be done with that project outcome. As a simple example, students might say that the project outcome is "improved accuracy in data entry" when what they mean one supposes is that in their project they will design (say) a new training programme that will be used to get the real work target of improved accuracy.

Speculation and Personal Theory – students are encouraged to speculate about problem causes and solution routes to arrive at a personal theory about the problem theme and how it might best be resolved leading to a suggestion of an expected form project outcome. A reader expects to see some indication as to what form the project outcome will take and in addition some discussion of the form to at least show that it is likely to go some way to resolving the stated problem theme. Unfortunately, the form was often missing and even when the Research Design was consulted a typical reader could still not see what the project outcome was supposed to be. Here we want to see ONE major form outcome for each project. (See workbook 6 section 6.5).

Research Question - either missing, badly worded or multiple questions offered (sometimes all in one sentence). One common mistake was to ask a question in the form (or some equivalent) of "is it possible...." - the point is that in such questions the answer is almost always that it is possible so the research effort becomes pointless. (See workbook 6 section 6.7 and 6.9)

Process for Generating Primary Data - this is a key element in any project as it is essentially the main activity used to unlock the primary data. It is useful to discuss this process briefly in the introduction since that allows readers to link the problem theme and therefore see what data you are likely to be looking for.

9.8.2 Project Introduction – Engineering Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem Theme - there was either no discussion or poor discussion of what problem theme the application being built was supposed to resolve. When this happens it is almost impossible for a reader to get any grasp of what the project is really about. (See workbook 6 section 6.2 and 6.5)

Functional Description - many students could not provide a short functional description of the application they were going to build. The most common thing for students to do instead was to provide an overview of the application architecture. This is hopeless as architecturally almost all Engineering projects are the same in that they typically have a database and a webpage for example. This implies that students cannot or do not want to make a distinction between how an application is built and what its purpose is.

9.8.3 Aim and Objectives

In many cases these elements were missing altogether. In other cases one could barely link the aim to the Research Question or application description. However, of most concern was an apparent inability in many students to write a coherent and reasonable set of objectives. Not to be able to write an aim and more particularly objective is representative of a gross error and it should never occur in Master's level work.

Aim - usually composed in a reasonable way but there does seem to be an inclination in some students to cram everything into the aim as if they are some kind of superman. The recommendation is to have just ONE clear activity mentioned in the aim and that should be accompanied by a just one clear outcome for the aim. (See workbook 6 section 6.11, 6.11.1)

Number of Objectives - often there were far too many to be in any way practical for one student in the time available and often this was because they were all expressed at different levels of project resolution.

No Visible Outcome - there were many, many cases where the objectives had no visible outcome. Far too often we got phrases such as: "To understand...." or "To analyse...." without any object to the sentence so there was no outcome that was visible. Without a named outcome there is no way that the objectives can be seen to have been completed. (See workbook 6 section 6.11)

Not Project Bounded - there were many students who cited operational objectives as outcomes. For example it was common to see lines such as such things as "To improve the workflow in the invoicing section". Here is a case where such an outcome cannot be written into a document or be in practical terms viewed and so cannot be used in a project. Typically, unbounded objectives refer to something that might happen based on the project outcome after the actual project has been completed (See workbook 6 section 6.11)

Objectives as Requirements - very commonly but still rather worryingly, many students, on Engineering projects, seem to think that objectives are the same as application requirements. (See workbook 6 section 6.11)

Objectives as Benefits - less commonly but still rather worryingly, many students, on Engineering and study projects, seem to think that objectives are the same as benefits. For example, in a study project on CRM systems what one often finds in place of project objectives is a list of benefits of implementing CRM. Similarly, for Engineering projects we see objectives written as a set of benefits of using the application being built later on in the real world. (See workbook 6 section 6.11)

9.8.4 Literature Review

In research the literature review is regarded as being essentially preparation of the mind. It follows, that to be serious about this step one has to be evaluatory and reflective as you read and write. Ideally one needs a strong theme which is used to weave an expository and exploratory discourse that unites and builds one's understanding and ideas with what has been written by other authors on one's core topic area.

For projects a full literature review is only needed in the case of a study project. For Engineering all that is required is a thorough overview of the application area. So for example, if an application were about Insurance brokerage then all that is required is a description of what brokerage is but only to the level necessary to understand the requirements. With this aim in mind: (See workbook 5 but section 5.2 and 5.6 should be studied with care)

Structure - many reviews were poorly structured and one often felt that the students had just written down the material as it occurred to them without any thought as to a wider readership.

Theme - often there was no detectable theme connecting the various sections of the review narrative and a reader would therefore be forced to guess and see how all the various elements were connected.

Value Added - the most common flaw was to see a review that was entirely or almost entirely made up of quotations, paraphrases or summaries so that the 'hand' of the student was not detectable anywhere in the work. Such work is not evaluatory and gives no indication whatever that the student has learned anything of value or indeed anything at all. It is often the case that one feels the student has no notion of the literature being a driver that may mean they have to accept new knowledge, gain further experience, modify existing knowledge or even abandon what they thought was sacrosanct and sadly no belief that their own views and experiences are also important.

Citation Style - two things are evident here. Firstly, one finds that too often citations are limited to the Literature Review. Secondly, the actual style used is very poor and commonly we see the form (Burk, 1992 p45) placed at the end of a sentence or paragraph. This is not acceptable and can only mean the whole paragraph has been paraphrased. The ONLY correct use of this bracketed style is in a passing reference to a text. (See workbook 8)

Worthless Quotes/Paraphrases - it is unfortunately only too common to see an appeal to some text or other for information that tells you either common knowledge or makes an obvious observation and so the citation is worthless and is representative of weak scholarship and laziness where a student is just trying to add a citation because he knows that such things are desirable. For example, quoting an author who says that "Object Orientation is now routinely used in software construction" is representative of common knowledge or quoting an authors who "says change is inevitable in organisations" is something that one might regard as obvious.

9.8.5 Research Design

These were often far from satisfactory and often read like a joke delivered without the punch line. The students are taught that essentially there are two phases. The first phase is the process used to get primary data items that are formed into a collection. Once the collection phase is completed we move on to the second phase of processing where the collection of primary data is processed to get an answer in the form expected. Particular points are:

Research Phases - In many case students were unable to distinguish the processing needed to get a collection of primary data and processing of the collection of primary data to get an outcome. It is quite common to see these two phases ignored or become competed muddled leading to a poor research outcome because the student loses his/her focus and often appear to have no clear idea what they are doing. The phases are:

Phase 1 - a process or processes used to define and create a primary data collection. It typically has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the data and present the data.

Phase 2 - a process or processes used to manipulate the collection of primary data to get the form of answer expected.

No Outcome - often it seemed as if the student had no idea what form of outcome to expect so when one looked at the processing there was no sense that the primary data was being transformed into the required form of outcome.

Primary Data - many students seem to have only a vague notion of what primary data is and will often, very often, confuse or think that primary data is the same as the method of collection. This confusion is often evident with some students thinking that only questionnaire data could possibly be primary data.

Primary Data Definition - Primary Data is new data in the sense that it will not exist as a collection until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data collection is representative of some aspect of the area under investigation and can be processed to get a defined form of outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

For example, one student took the definition and then read through an accounting system manual for his company and extracted all the functions and claimed that was primary data because he was going to use it to define what an accounts package should have by way of functionality but seemed unable to see that the manual had effectively done that already. (See workbook 6 section 6.6)

Research Method Justification - often students could not distinguish between Research Method and Data Collection Protocols. Research Methods are frameworks such as Case Study, Experiment, Action Research and so on. Collection protocols are based on: interview, questionnaire, observation, role playing, seminars, focus groups and so on. The sorts of justifications used are of the form "I have chosen case study because Saunders (2005, p92) said case studies are good... This is hopeless and implies no real thought. Justification must be built from a sound understanding of a particular Research Question, its expected form of outcome and the Primary Data needs and at least an overview of which method is likely to be best in a given situation. (see Workbook 7)

Practicality - many plans were over-complicated with students trying to use multiple methods and then ending up with masses of data they had no idea what to do with. There is only limited time and so students should be encouraged to focus on just one Research Method although of course several protocols may be involved.

Data Collections - in many cases all an examiner was able to see were results but often one simply could not tell if any primary data collection was involved and the results just seemed to appear 'out of the air'. The marking guide is quite specific and projects must be clear about both processed data and raw primary data collections. Without this we cannot feel confident that students have done any actual research. Typically, the collection of primary data is placed in an appendix and might be in the form of a summary table of questionnaires results or summarised transcripts. Correspondingly, the processed primary data collection is expressed as charts, graphs, tables, reports and so on in the body of the project report.

Processing - this is one of the most disappointing elements. Processing is all about transforming your collection of primary data into the form of outcome expected. Far too often all we see is the processing of individual primary data items with no attempt or very weak attempts to really supply an answer to the Research Question in the form that was specified.

Location - there were quite a few projects where it was more or less impossible to see where the primary data came from and often this was accompanied by a very ordinary set of results that could have been written by almost anybody with a superficial knowledge of the subject area.

9.8.6 Research Results Processing

There were some very good examples but often this section was very routine and very disappointing.

Repeating - it was very common to see a chart for example, displayed and then underneath the student simply repeated the data that was in the chart in words. Such a practice is worthless. What any data related narrative is supposed to do is to tell the reader what the data means and what implication it might have - that is we expect to see some analysis and evaluation of the data in terms of the Research Question.

Focus - the focus of processing the primary data is to create a kind of transformation that generates from the collection of primary data the expected project outcome - unfortunately, this aspect was often absent. Typically in a survey for instance we have page after page of charts analysing individual data items but no attempt to sum it all up and reach a conclusion based around the Research Question.

9.8.7 Evaluation and Conclusions

These sections in a lot of student work are indistinguishable. The reason there are two sections with marks attached is because:

Evaluation - here one focuses specifically on the project outcome and research methods - that is we evaluate our product (outcome) and the methods used to generate it. Notice here this is NOT about generating the outcome that would have been done in the research processing section

Conclusions - here the attempt is made to say what it all means - that is trying to generalize the findings. So for example, suppose the outcome is about the use of Agent technology in eCommerce web sites then in conclusions one might try to say what a particular project outcome means for any eCommerce site or in fact any website. In a similar kind of way, if a particular application had been built we might try to say whether it might be applicable in other situations or whether some features of the design can be transferred to all applications of that type.

9.8.8 Ignorance of Project Marking Criteria

Many students show an almost complete disregard for the way a project is marked and so often automatically lose marks. Students must therefore carefully study the marking forms so that they know what components are regarded as essential to any project and therefore carry marks. (See workbook 11 or 12 as appropriate)

10. WORKBOOK 10 – FORM: PROJECT SUBMISSION

This form **must** be completed and included in your project submission. If you are unable to tick every box then your work is not ready for submission. If boxes are ticked and it is subsequently found that the relevant element is not present it will be taken as a deliberate attempt to falsify the record and regarded as a fail.

Project Word Count	Exclude appendices. If maximum is exceeded marks may be lost or the project rejected
	The report length is within the stated guidelines (15,000 words maximum excluding appendices)
	I have included all making elements indicated in workbook 11 Or 12 as appropriate and noted the marking guidance notes
	I have studied the guidance notes on common project faults found in section 9.6
	I have prepared two bound copies of all my project work including any separate appendices
	I understand that I may use one or both sides of the paper when printing the report.
	I have included a full contents list, table list and diagram list all numbered consistently
	I have used good quality A4 paper, normally in portrait orientation with a weight between of 80 and 100gsm.
	I have made sure that the pages are in the right order and none are missing
	I have used MS word .doc format
	I have formatted the front cover and title page as required and added the necessary plagiarism declaration.
	All my text is single line spaced at 6 lines per inch/25.4 mm.
	All my main text, including headings is in 12-point font (Arial Narrow is recommended)
	All my text in tables and diagrams is 10-point font (Arial Narrow is recommended)
	All main text is right and left justified
	No headings at whatever level are indented
	Headings are NOT followed by a blank line
	Headings are in the same font and size as the main text but are shown in bold type
	No numbered headings are orphaned (that is all heading must be followed by some text not immediately by another heading)
	I have used a single blank line to separate paragraphs
	All chapters and appendices are numbered sequentially (1, 2, 3,...)
	All subsections are numbered (2.1, 2.2,...) and none of my sections numbers exceed three levels (1.2.1, 1.2.3 ...)
	All my margins: (top, bottom, left and right) are 20mm
	Pages have centred footers in 10-pt Arial Narrow: Page 12 of 97 - J.J. Letto HEMIS No. 567543 Submission Date: 2004/05
	I have cited other people's work properly using the Harvard APA format
	I have included all citations in my list of references
	My abstract accurately summarises all of the report, not just parts of it
	All my chapters and appendices start on a new page
	I have included appendices, where appropriate, covering: project specification, Project Plan, Requirements document(s), design document, screen shots, source code, user documentation, test results, evaluation results, questionnaires, etc.
	My supervisor has read each chapter as the work progressed.
	My supervisor has read the whole report
	I understand that indented sentences can be used where appropriate but bullets are not recommended (see 9.3.1)
	I understand that page headers are not required
	I understand that each of my chapters should start with an introductory section that explains what the chapter is about
	I understand that each of my chapters should end with a summary and a helpful link to the next chapter
	I have fixed a copy in .doc format of the project document and any appendices on floppy/CD/DVD to my project submission
	All my primary data (including requirement data) is original to this study and collected by me for this specific project purpose
	Engineering Projects only - I have included an executable file of my application on an attached floppy/CD/DVD
	Engineering Projects only - Application Operating instruction are on the attached floppy/CD/DVD as well as in the appendix
	Engineering Projects only – In my application I have not used illegal copies of any software or included any software where there is an expiry date which may render the application inoperable in the future.
	Engineering Projects only - I understand that the copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If, and only if, this is not possible then I have included in my project a supervisor signed set of screen shots in the appendix confirming that he/she has viewed the application in action.
Signature of Student.	Date.

11. WORKBOOK 11 – FORM: STUDY PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

STUDY STYLE		Postgraduate Project Marking Form						STUDY STYLE	
Name of Student							HEMIS No.		
Brief Project Title							Total Mark	%	
Recommendation	If the mark awarded is a fail circle your opinion						Re-Work	New Topic	
Name: Supervisor									
Name: Marker									
Marker Status	Supervisor		Moderator		3 rd Marker		Re-Marker		
Project Unit	PJ.NCC								
Plagiarism	N	Y	Is PLAGIARISM or another unfair act is suspected						
External Examiner	N	Y	Refer to the External Examiner (if "Y" add comment in section G)						
Content	Y	N	Can you confirm that this project fulfils the criteria for the Unit						
References: See Workbook 11 for detailed marking guidelines and Workbook 14 for general expectation and grade criteria notes									
Section A - Marks for Planning and Preparation							Weight	Mark	
1.	Project specification, including project plan						5		
2.	Review of the topic area literature						15		
Sub-Total							20		
Section B - Marks for Project Introduction									
3.	Presenting problem and its exploration including the Research Question						5		
4.	Discussion of the project's scope, scale, aim and objectives						10		
Sub-Total							15		
Section C - Marks for Project Primary Data Research and Outcome Generation									
5.	Selection and justification of Research Method						5		
6.	Primary data collection plan including data specification						10		
7.	Primary data processing plan to get expected outcome						10		
8.	Presentation and discussion of the collection of Primary Data						10		
9.	Description and discussion of main project outcome						10		
Sub-Total							45		
Section D - Marks for Project Evaluation and Conclusions									
10.	Evaluation of the project outcome (Project Specific)						5		
11.	Evaluation of project practice (Project Specific)						5		
12.	Statement of conclusions and reflections (Project Generalisations)						10		
Sub-Total							20		
Section E – Qualitative Assessment matrix based on University Grade Criteria									
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words			
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless			
3.	Report structure	very poor	poor	satisfactory	good	excellent			
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report			
5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours			
6.	Project idea	trivial	easy	modest	challenging	Difficult			

7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Primary data collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Data processing	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
14.	Main project outcome	Worthless	obvious	useful	original	exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Study Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes found in Workbook 14.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.2 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the topic area literature

Reference: Workbook 5 section 5.2 and 5.6 in particular, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers and generally be focused on the central project topic. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and its exploration including the Research Question

Reference: Workbook 3 section 3.3 and 3.5.1, Workbook 6 sections 6.2, 6.6 and 6.7 and Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Research Question with a defined form of answer (project outcome). It is very common to see an expression of a problem as "my problem is to find a solution to..." or expressed in such a way that it is in effect a solution and such expressions are indicative of students who do not know what the problem is but nevertheless know what the solution is. Similarly, students who list multiple problems, have no Research Question (or a very poor one) and do not discuss the form of outcome expected are embarking upon projects where there is no clear focus and these typically fragment when it comes to the core research and one most often cannot find any clear project outcome later in the work. It is also useful at this stage if there is some indication of the Basic Activity for Generating Data (BAGeD) so that one can feel sure that the student is aware of what primary data they need in order to generate the intended outcome.

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.2 (example), Workbook 6 section 6.1 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition, expected form of outcome and Research Question all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Selection and justification of Research Method

Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful choice of Research Method focused on resolving the stated problem theme. In practice this implies a consideration of primary data needs, location of primary data and the collection protocols that might be used. Markers should guard against rationales that amount to saying that some text book or other said method X or Y was good for certain kinds of scenario – that is copies of generalisations about Research Methods found in books do not amount to a rational for a specific research situation. Furthermore, markers need to feel confident that the student understands the distinction between a Research Method and the collection protocols used within them.

6. Primary data collection plan including data specification

Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

This is a crucial stage in a research based project and markers must be confident that the plan is practical. A marker must look for a clear core activity represented by a statement about of BAGeD and that core activity should be surrounded by whatever other processes are needed to ensure reliable collection of the primary data. The whole primary data collection plan has four steps which must be visible in the project document: data definition, data location, data collection and how the whole collection of primary data is to be presented. Markers should also take care that the formation of a collection of primary data is not confused with the processing of it to get the stated project outcome.

7. Primary data processing plan and presentation of the expected outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for clear evidence that the student has taken the collection of primary data they obtained earlier in the project and now process that whole collection to get to a clear presentation of the project outcome. It is therefore important that markers can see what processes were applied to the collection of primary data to get the outcome – without this process visibility there is no evidence as to how the project outcome was actually obtained. Markers should be wary of processing plans that say such things as “I will look at the data” or “I will analyze the data” or “I will use SPSS” as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same data collection they could apply the same processes and get the same or at least a very similar outcome.
Markers should also be aware that very often students will often process individual data items – such as might be found on a questionnaire, but never get to a point where the stated project outcome is derived from the collection of data.
8. Presentation and discussion of the collection of Primary Data
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for visible signs of the collected primary data. The primary data collection is most often presented in tabular form in the appendix and might be displayed as graphs, charts, tables or diagrams in the main project document.
9. Expression and description of main project outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
The intended project outcome must be clearly visible – for example if the intended outcome is a model then that must be clearly shown in some acceptable form and be based on the processing plan outline in section 7. Markers must therefore take great care that the presentation of primary data and the processing of individual data items in the collection are not offered as a substitute for the student generating the intended project outcome.
Section D - Marks for Project Evaluation and Conclusions
10. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project outcome so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution (project outcome) or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project outcome. The section is not intended for vague thoughts about the topic but a considered evaluation of the project outcome when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
11. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate here. This section is important as this is where one expects to find some information on what the student has learned about the way they work and the tools they used. It is unfortunately often the case that students have very little idea about what they did apart from stating vague activities such as “look at”, “analyze” or “use SPSS” so without anything concrete to evaluate they resort to the routine and say “the survey process went very well” or “my case studies generated useful data” or else they simply ignore this form of evaluation altogether. Evaluation of project practice is difficult and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking ‘how did I do it’, ‘was it successful’ and ‘could I or should I on reflection have done it another way’. Additionally, one needs to be aware of any constraints involved, including time management and particular skills that might have impacted on the use of best possible practices.
12. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a project outcome was based on case studies and the outcome was a review of IT outsourcing in Hong Kong then here we might expect to see the student consider the outcome he obtained which refers to Hong Kong and then consider and discuss whether that outcome has wide applicability, for example, to China, South East Asia or even the world as part of a Global economy or is it just specific to that local situation. Essentially, one is asking what do the outcome ‘mean’ when set in a wider setting. It follows that the focus of awarding marks here is for project generalisations.
It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such as future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

12. WORKBOOK 12 – FORM: ENGINEERING PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

ENGINEERING STYLE		Postgraduate Project Marking Form				ENGINEERING STYLE	
Name of Student						HEMIS No.	
Brief Project Title						Total Mark	%
Recommendation	If the mark awarded is a fail circle your opinion					Re-Work	New Topic
Name: Supervisor							
Name: Marker							
Marker Status	Supervisor		Moderator		3 rd Marker		Re-Marker
Project Unit	PJ.PEA						
Plagiarism	N	Y	Is PLAGIARISM or another unfair act is suspected				
External Examiner	N	Y	Refer project to the External Examiner (if "Y" complete section G)				
Content	Y	N	Can you confirm that this project fulfils the criteria for the Unit				
References: See Workbook 12 for detailed marking guidelines and Workbook 14 for general expectation and grade criteria notes							
Section A - Marks for Planning and Preparation						Weight	Mark
1.	Project specification, including project plan					5	
2.	Review of the application/product area and its client/business setting					10	
Sub-Total						15	
Section B - Marks for Project Introduction							
3.	Presenting problem and outline proposal					5	
4.	Discussion of the project scope, scale, constraints, aim and objectives					10	
Sub-Total						15	
Section C - Marks for Project Primary Data Research and Outcome Generation							
5.	Detailed requirements collection plan based on proposal					5	
6.	Analysis of requirements: functional, performance, technical and usability					5	
7.	Presentation, analysis and discussion of the design					10	
8.	Discussion of build process and design implementation					10	
9.	Application testing process and results					5	
10.	Implementation plans					5	
11.	Attributes of the project artefact (e.g. quality, reliability, etc)					10	
Sub-Total						50	
Section D - Marks for Project Evaluation and Conclusions							
12.	Evaluation of project product against requirements (project Specific)					5	
13.	Evaluation of project practice (project specific)					5	
14.	Statement of conclusions and reflections (project generalisations)					10	
Sub-Total						20	
Section E – Qualitative Assessment matrix based on University Grade Criteria							
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words	
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless	
3.	Report structure	very poor	poor	satisfactory	good	Excellent	
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report	

5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours
6.	Project idea	trivial	easy	modest	challenging	difficult
7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Requirements Collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Design Expression	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
15.	Artefact Evaluation	worthless	obvious	useful	original	Exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Engineering Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.1 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the application/product area and its client/business setting

Reference: Workbook 5 section 5.2 and 5.6, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers. In Engineering projects the expectation is that the review will focus on the application area and be in enough detail to at least understand and gather the requirements. It is permitted to include technical material if they have a special or unusual significance to the application area but in so doing students must be aware that the routine inclusion of what at this level might be regarded as common knowledge in computing/IT will not attract any marks. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and Outline Proposal

Reference: Workbook 3 section 3.3 and 3.5.1 Workbook 6.2 and 6.5, Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Application Outline expressed as a functional description. It is very common to see an expression of a problem as "my problem is to find a solution to..." and this is indicative of students who do not know what the problem is but nevertheless know what the solution is. Students who list multiple problems, have no functional description (or a very poor one) are indicative of projects where there is no clear focus and these typically fragment when it comes to requirements gathering and often end in a very trivial application. Markers should be aware that students may avoid giving a functional description and instead offer a generic architectural one and this must be penalised as the student clearly does not know what function the application supplies

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.1 (example), Workbook 6 section 6.11, 6.9 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition and Application Outline all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Detailed requirements collection plan based on proposal

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful consideration of the Requirement Gathering process focused on obtaining sufficient information to build the intended application and resolve the stated problem theme. In practice this implies a consideration of application functions, location of requirements data and the collection protocols that might be used. Normally in research one would expect a rationale for the choice of Research Method but for Engineering projects it is taken for granted that the method is requirements gathering. Instead one should look for a clear focus on constructing a feasible and comprehensive requirements document based on the application outline. Furthermore, markers need to feel confident that the student understands the distinction between Requirement Gathering as a Research Method and the collection protocols used within it.

6. Analysis of requirements: functional, performance, technical and usability

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers must look for a clear Application Proposal and a requirements catalogue. Here one needs to see a discussion of the requirements to ensure they are credible (realistic), comprehensive, complete and stakeholders have been considered. One might also usefully consider the approach that was taken to gain them and whether they are of the form of strategic, tactical or operational.

7. Presentation, analysis and discussion of the design
Reference: Workbook 9 sections 9.6.5 and 9.6.6 and Workbook 7 section 7.9
Marks are awarded here for clear evidence that the student has taken the requirements obtained earlier in the project and processed them to get a suitable design. Therefore, markers must be able to see a clear link from requirements to design and where necessary observe how the requirements were processed. Markers should be wary of processing plans that say such things as "I will look at the requirements" or "I will analyze the requirements" as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same requirements they could apply the same processes and get the same or at least a very similar outcome.
8. Discussion of build process and design implementation
Reference: Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for a rational discussion as to what architecture, components, languages and tools and so on are needed to best implement the design. This discussion may also imply the various situation constraints have to be considered as well.
9. Application testing process and results
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers must look for evidences of a testing plan and a consideration of test results. Typically the plan and results are placed in the main project document in outline form with the details in an appendix. Often students will just discuss white or black box testing or regression testing or something similar but without any actual test plans or results – in such cases marks should not be awarded as these materials is considered common knowledge at this level – however brief references to it are permitted.
10. Implementation plans
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers should look for a comprehensive implementation plan – it need not be extensive or in minute detail but it should cover installation, user training, data conversion/loading, change over, user acceptance and hand-over.
11. Attributes of the project artefact (e.g. quality, reliability, etc)
Reference: none
The intended project application must be clearly visible and available to run directly from a disc or DVD. Markers are to award marks based on their perception of the general quality of the application if they were to put themselves in the place of a user. Assessment may then consider colour scheme, ease of use, operating instructions, presentation (does it look as if its finished), speed, etc.
Section D - Marks for Project Evaluation and Conclusions
12. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project application so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project application. The section is not intended for vague thoughts about the situation or application but a considered evaluation of the project application when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
13. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate. This is where one expects to find some information on what the student has learned, the way they work and the tools they used. It is often the case that students have very little idea what they did apart from being able to state vague activities such "look at" or "analyze" so without anything concrete to evaluate they resort to the routine and say "the survey process went very well" or "the UML modelling was straightforward" or else they simply ignore this form of evaluation. Evaluation of project practice is difficult because the student must ask searching questions related to process success and the notion of good and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way' or "what were my constraints".
14. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a an application was for eCommerce selling shoes it might be possible to ask what aspect of that application could be re-used to sell other product. It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

13. WORKBOOK 13 – FORM: PROJECT MARKING RECONCILIATION

The form shown below is included for reference only so that you can see how your project will be marked.

Project Mark Reconciliation Form		Final Agreed Mark (%)	
Name of Student			
Brief Project Title			
Name: Supervisor			
Name: Second Marker			
Name: 3rd Marker			
<p>Cause – in this box, describe, for each applicable section, why the marking disagreement occurred.</p> <p>Rationale – in this box, If a mark can be agreed, explain the rationale used to reach agreement. Please note that it is only necessary to agree the total mark for each section not individual category marks.</p> <p>Irreconcilable - If you cannot agree a mark leave rationale blank and it will be filled in by a third marker who will place a tick in the small square box.</p>

14. WORKBOOK 14 – SUPERVISION AND MARKING GENERAL GUIDANCE NOTES

1. **Presented Work** - Marker's are reminded that any marks awarded must be solely based on the assessment of work presented within the mark categories listed on the mark forms. It is not permitted to award marks for "hard worker" or "tried very hard" or "was a good student" or any similar observation as there are no relevant mark categories and this kind of criteria is almost impossible to evidence.

When an Engineering artefact is presented it should be viewed in action to ascertain the mark for "Attributes of the Project Artefact". The copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If this is not the case then markers must assume that there is no evidence for the application and set the mark accordingly.

2. **Word Count** – on the project submission form there is a space for a word count (excluding appendices) and if this is exceeded then it is indicative of a deliberate attempt to go beyond recommendations and you may therefore find that it leads to laboured descriptions or inclusion of irrelevant material in the project document and you should therefore mark accordingly.
3. **Structure** – mark categories do not necessarily represent chapters in a project document and so Marker's need to be aware that a particular project may be structured in a way that does not correspond to the sequence presented on the mark forms (though it is recommended to do this when possible). However, all the elements on the marking form must be visible in the work presented.

Although it is recommended that the mark form sequences be followed in the project document that does not mean that there has to be a chapter for each mark category. Students, therefore, should be encouraged to merge sections in order to produce a concise document. For example, it is perfectly possible and reasonable to merge the two evaluation sections and conclusions into one chapter as long as the relevant mark elements are still visible.

4. **Appropriateness** - any work presented must be within the prescribed subject area for the course. If a marker suspects that this is not the case then they should consult with the relevant course leader for clarification. In such accepted cases markers must regard the primary data and its processing as not being appropriate and mark with that in mind.
5. **Evidence** - the project report or appendix must contain sufficient evidence that the core project research work has been done (not the literature review). That is, in the case of study project a marker must be able to see the primary data collection appropriately presented (usually in an appendix). In the case of Engineering projects it must be possible to see a suitable requirement document or catalogue (possibly in the appendix). Once the primary data is visible then it must also be possible to see how that data was transformed into the intended project outcome.
6. **Literature Support** - when marking Literature Reviews their content must be seen to be focused on the topic area and address clearly the associated problem theme without any irrelevant material with the intention of offering a concise discourse that is focused, relevant, authored, measured, evaluatory and expressed as a dialogue. (see section 5.1)
7. **Grade tables** - markers must be aware of the criteria associated with awarding a given overall mark as they may be required to justify it to the UAB in terms of the criteria stated in the table shown below.
8. **Process** – when marking it is important that the process used to get an outcome by the student is visible in the project document. In practice this means that it is possible to perform the following trace: presenting problem, discussion of how problem might be resolved, suggested form of project outcome, research design and execution, generation of stated outcome, evaluation and conclusions – viz:

Engineering – typically, the process starts with a business related or technical problem theme leading to a research plan for the collection and discussion of requirements and their transformation into a suitable design and associated architecture. From this there should follow a build, implement and testing process with the whole project completed with suitable project specific evaluations and conclusions containing generalisations.

Study – typically, the process starts with a business or strategic IT related problem theme leading to a research plan for the collection and discussion of primary data and its transformation into an outcome that would resolve or go some way to resolving the stated problem theme. The whole

project is then completed with suitable project specific evaluations and conclusions containing generalisations.

Marks	Master's Level Grade Criteria
70 – 100	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Excellent work - able to express an original reasoned argument in a lucid manner by reviewing & critiquing a wide range of material. Original, critical thinking based on outstanding insight, knowledge & understanding of material. Material contributes to current understanding & is of potentially publishable quality in terms of presentation and content ▪ Wide reaching research showing breadth & depth of sources
60 – 69	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Clear, balanced coherent critical & rigorous analysis of the subject matter. Detailed understanding of knowledge & theory expressed with clarity ▪ Extensive use of relevant & current literature to view topic in perspective, analyse context & develop new explanations and theories
50 – 59	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Detailed review and grasp of pertinent issues & a critical contextual overview of the literature. Thorough knowledge of theory and methods & uses this to underpin arguments and conclusions ▪ Confidence in understanding and using literature
40 – 49	<ul style="list-style-type: none"> ▪ Demonstrates grasp of key concepts & an ability to develop & support an argument in a predominately descriptive way with valid conclusions draw from the research ▪ Familiarity with key literature which is cited and presented according to convention ▪ Logical & clear structure, well-organised with good use of language and supporting material
0 – 39	<p>FAIL – Some knowledge of relevant concepts & literature but significant gaps in understanding and/or knowledge. Little attempt at evaluation, conclusions vague, ambiguous & not based on researched material. Limited or inappropriate research. Deficits in length, structure, presentation &/or prose.</p>

This form may be used by you to feedback to the University your experiences in the courses. It is normally sent to your tutor at the end of the course.

Page 88 of 88 Research Methods Workbooks - Release 3.2c Dated December 2006©

Researching: Some different methods and approaches

Dr Carl Adams

For Research Methods Residential School, 13th
September 2006
School of Computing

Aim

- To develop understanding of research issues for different research methods

Agenda

Three research projects using different methods:

- 1) Survey – mobile use questionnaire
- 2) (building on) Mixed methods, Interviews, observations – Confirmation case study
- 3) Secondary data analysis – Biases in development techniques

Main issues, questions (+questions throughout!) ...

Survey – mobile use questionnaire

- Background
- Research questions
- Research method
- Survey ... what type, who to survey, how many, how to process the data / interpret the results ...?
- Research process
- Challenges

The problems/ question?

How attached were people to their mobiles?

- Examines the existing relationship people have with their mobile phones
- Likely impact on developing trust in the 'mobile' relationship

The research study

- Questionnaires, paper based
- Distributed to students at Universities in three different countries (France, UK and China) ... mainly UoP
- Now over 1500 responses
- Target students (as an interesting user group) ... but big issues!

Mobile Use Questionnaire

- Double-sided A4 sheet
- Mostly 'tick boxes'
- Anonymous responses (but age, gender, nationality details)
- Questions to examine attitudes and attachment to mobile phones
 - 'support mechanism'
- Questions about watches (provided a comparison)

*If you left home and two minutes later realised you have left your **mobile** phone at home, would you go back for it if you were:*

	Yes	Probably	Probably not	No	Don't know
Going on a long journey?					
Just going down the shops?					
Going to work, college or school?					
Going to work, college or school and were already 5 minutes late?					

- How robust is this?

Confirmation case study:

- Background (building on previous mixed methods, Interviews, observations)
- Research questions
- Research method
- Case study ... what type, who to choose, how long and what data to collect (and how), how to process the data / interpret the results ...?
- Research process

Choice of theoretical framework:

Prospect theory (Kahneman and Tversky 1979)

- 'tried and tested'
 - several examples
 - guidance on conducting robust, repeatable research
- not applied to the information systems field before
 - scope for novelty/adding to knowledge

Prospect Theory's value function, from Kahneman and Tversky (1979)

Previous research activity (and theoretical framework) provided guidance on ...

- What to look for (observations)
- What to ask (interviews)
- What type of case study (a 'good' example)

- How robust is this?

Secondary data analysis – Biases in development techniques

- Background
- Research questions
- Research method
- Secondary data ... what type, what to include / not include, how many, how to process the data / interpret the results ... ?
- Research process
- Challenges

The problem ...

Techniques (lots of them ...)

- | | |
|---------------------------|---------------------------------------|
| • Rich pictures | • Entity life cycle |
| • Root definitions | • Object orientation |
| • Conceptual models | • UML |
| • Cognitive mapping | • Case-based reasoning |
| • Entity modelling | • Risk analysis |
| • Relational modelling | • PERT Charts |
| • Normalization | • Gantt charts |
| • Dataflow diagramming | • Lateral thinking |
| • Decision trees | • Critical success factors |
| • Decision tables | • Scenario planning |
| • Structured English | • Future analysis |
| • Structure diagrams | • SWOT |
| • Structured walkthroughs | • People techniques |
| • Matrices | • Stakeholder analysis |
| • Action diagrams | • Joint application development (JAD) |
| | • ... |

Techniques have evolved ...

- Many new techniques
- Some based on the earlier 'traditional' techniques
- 'good practices' evolving to address the 'current' development environment
- Plus some re-badging

Techniques seen as neutral...

- Techniques are generally seen as providing neutral support for developers
- We challenge this view ...
(based on strong evidence from the Psychology lit.)
- Earlier work ...
 - classification based on visual/language and paradigm/process influences
 - technique are likely to influence problem cognition

E.g. Conceptual blocks ...

- Perceptual Blocks**
- Cultural and Environmental Blocks**
- Emotional Blocks**
- Intellectual and Expressive Blocks**
(conceptual blocks, adapted from Adams 1987)
- ... provided a starting point

Group	Perceptual Blocks	Emotional Blocks	Cultural and Environmental Blocks	Intellectual and Expressive Blocks	Visual representational attributes	Language and discourse attributes	Individual attributes
Brainstorming	Low	Low-Medium *	Low	Low-Medium High *	Low-Medium	Low-Medium **	Low-Medium High **
Relationship	High	High-Medium *	High	Low-Medium High *	High	Medium-High	Low-Medium High **
Scenario	Low-Medium	Medium *	Medium	Low-Medium High *	Medium	Medium	Low-Medium High **
Storyboard	High	High (lack of task flexibility) *	A High	Low-Medium High *	High	High	Low-Medium High **
Matrix	High	High-Medium *	High	Low-Medium High *	High	Medium	Low-Medium High **
Conflict	Low-Medium	Medium *	Medium	Low-Medium High *	Medium	Medium-High	Low-Medium High **

Application ...

- Applied to around 70 techniques
 - (appendix in paper)
- suggested use techniques from different categories
 - reduce risk of cognitive/ conceptual biases due to framing and scooping influences.
- likely to be further influences,
 - individual biases towards different techniques (or tasks within them), negative versus positive framing and a range of perceptual blocks.

- How robust is this?

Main issues?

- Research process
- Research questions?
 - Best research method to address question &
 - Best type of data to address question
- or
- Realistic research method to address question
 - Realistic type of data to address question

Main issues?

- Data collection ... think about how you are going to analyse the data before you collect it
- Data analysis ... interpreting the results
- Plus lots of other issues ...

Main issues?

Good research (publishable, good marks etc), should have:-

- Good (robust, realistic) methods, data collection, and analysis
- Originality, contribution
- AND Good foundations ...research questions, supporting literature, theory

Thanks for your time,

Any (more) questions?

Committee Structures and Responsibilities

The University has a committee structure that manages all aspects of courses. This includes day to day running of the course, assessment, award of credits and award of final degree. Outlined below are the committees relevant to this course and details of what their purposes are.

Board of Studies (BOS)

This Board has direct responsibility for the academic validity, coherence and quality of the course. Membership consists of course leaders, the head of department, facilitators, service providers, students and student representatives (designated from each cohort). They are held at least twice per annum using a synchronous chat room.

Students and staff place items on the agenda via the discussion boards, and can attach documents if required. All students and academic staff are permitted to attend the online BOS and may contribute if they wish.

Unit (Module) Assessment Board (UAB)

This Board meets at least four times per year, but may exceptionally meet at other times in order that information to students on the results of assessment are not delayed. The Unit Assessment Board confirms the marks for each module and awards the credit points.

Board of Examiners (BOE)

This Board will consider all student results profiles and has the power to make appropriate awards to students who successfully complete their studies. The Board meets at least four times per year but may exceptionally meet at other times in order that information to students on the results of assessment is not delayed. Details on recommendations made in this meeting can be found in the Academic Regulations.

Quality Assessment and Feedback

We are always ready to make improvements to the structure, processes, assessment, resources and learning on the courses. In order to do so, a number of review mechanisms are used:

Module Review - on completion of a Module, teaching staff will normally review the Module with a view to possible improvements in materials, content and presentation. The review may be carried out in a number of ways but typically by means of an online feedback form.

Course Review - the Account Manager will normally carry this out at the end of your course. In most cases an online feedback form will be used. In general the review will cover four areas (programme of study, general topics, resources, teaching and learning.)

Account Manager - will review the discussion boards on a daily basis and will attempt to answer your questions, resolve difficulties or deal with complaints as soon as possible. If you wish your communication to be private you may use email services.

Board of Studies - will have a section on its agenda devoted to student matters and consideration of feedback.

Assessment

Both modules studied on this programme are assessed by coursework 100%. The assessment for the **Research Methods** module is in three parts as follows:

Assessment Part 1: Written Preparation for the project (70%)

Assessment Part 2: Statistics Questions (30%)

Assessment Part 3: Project Specification (approved/not approved)

In **Part 1** students will formulate a research question and perform a detailed analysis of the topic chosen, write a literature review, and outline a research method.

In **Part 2** students will answer a series of statistics questions.

In **Part 3** students will write an outline of the project they wish to undertake.

The **Project** module is assessed by a single piece of work in which the subject chosen is discussed comprehensibly and at length. The subject will be supported by a literature review.

To find out detailed information refer to the Module Specification (link on homepage) and within the actual online course material for that module.

External Examiners

Every award-bearing course in the University has an external examiner who is tasked to independently review the assessment procedures and standards. In order to carry out their function they examine a selection of marked continuous assessment work and sit on the Board of Examiners. All cases of failure are reviewed by them and their comments are always sought when recommendations for either deferral or referral are made. In addition, external examiners are non-executive members of the course team and their views on all significant course related matters will be sought.

Plagiarism or Other Malpractice

The term plagiarism is used to describe 'literary theft', of either ideas, or of the actual words, formulae, etc. of another person or persons. It is one of the worst things that one can be accused of in academic life as it is really a form of stealing or cheating.

It is normally expected that students will carry out research prior to completing an assessment. It is therefore permissible to use textbooks, lesson notes and to include (with appropriate citations) elements of published work and so on to support and prepare your own work. However, it is not permitted for you to use published or unpublished material as a substitute for your own work without acknowledgement. Published material includes texts you find in the library, lesson content, Internet web pages, documents belonging to your employer; indeed anything that can be defined as belonging to an author other than oneself.

Plagiarism, therefore, is defined as the attempt by a person to present the work of others as if it was their own. Such illicit presentation includes paraphrasing another author's work and copying from textbooks or journals without using quotation marks and citing the source.

Copying of notes or the work of other students is also considered as plagiarism even though the work being copied from is not published in the ordinary sense of the word.

There are two common forms of plagiarism, the most obvious one being where someone submits all, or part, of someone else's assignment as his or her own work. The second, and probably more common form is where an assignment contains unattributed ideas or passages from books, articles or lecture handouts. Sometimes this is deliberate, but often it is because the student is unaware of how they should use and reference source material in their work.

Penalties for Plagiarism

Plagiarism in written assignments is treated as a serious offence by the University in much the same way as cheating in an examination, and there are a range of regulations that address this issue. Where students are found to be guilty of plagiarism a range of penalties are available that range from a reduction in the mark awarded to the cancellation of the entire assessment. In all cases the matter is reported to the Board of Examiners. Persistent offences could lead to more serious disciplinary proceedings being instituted.

Outline procedure for suspected plagiarism

When a member of staff suspects a student of plagiarism the matter is brought to the attention of the course leader and the assignment is second-marked. If the second-marker also believes some, or all, of the work to be plagiarised then the student will be contacted by the Head of Department with details of the alleged offence, probably by email. The student has an opportunity to answer and refute the allegations. If the Head of Department believes that the offence is proved to have occurred sanctions may be applied. If the student feels that the allegation of plagiarism is unfounded then they have the right of appeal before a formal disciplinary panel.

Details of the full procedures relating to plagiarism, and for all forms of assessment malpractice, are to be found in the Handbook of Academic Regulations.

Grade Criteria (Level M)

General Criteria applicable to essays, reports and aspects of projects and dissertations

	Level M
80+	As below plus: Excellent work - able to express an original reasoned argument in a lucid manner by reviewing & critiquing a wide range of material. Original, critical thinking based on outstanding insight, knowledge & understanding of material. Material contributes to current understanding & is of potentially publishable quality in terms of presentation and content Wide reaching research showing breadth & depth of sources
70-79	
60-69	As below plus: Clear, balanced coherent critical & rigorous analysis of the subject matter. Detailed understanding of knowledge & theory expressed with clarity Extensive use of relevant & current literature to view topic in perspective, analyse context & develop new explanations and theories
50-59	As below plus: Detailed review and grasp of pertinent issues & a critical contextual overview of the literature. Thorough knowledge of theory and methods & uses this to underpin arguments and conclusions Confidence in understanding and using literature
40-49	Demonstrates grasp of key concepts & an ability to develop & support an argument in a predominately descriptive way with valid conclusions draw from the research Familiarity with key literature which is cited and presented according to convention Logical & clear structure, well organised with good use of language and supporting material
30-39	FAIL Some knowledge of relevant concepts & literature but significant gaps in understanding and/or knowledge. Little attempt at evaluation, conclusions vague, ambiguous & not based on researched material. Limited or inappropriate research. Deficits in length, structure, presentation &/or prose

Project Grade Criteria

The characteristics of different classes of project are given below. They have been adapted and extended from the assessment criteria for the Partnership Degree scheme and from those used at other universities. They show the characteristics typically shown by projects of a given standard. Where a report shows a mix of characteristics from two adjacent grades (e.g. 75% and 65%) then it is appropriate to award a borderline mark (i.e. 70%).

Grade	Typical characteristics
95% (outstanding)	<ul style="list-style-type: none"> ▪ Outstandingly thorough understanding of all concepts and of the distinguishing features and trends within the field of study. ▪ Shows exceptional understanding of the issues relating to the project. ▪ Clear structure (introduction, sections, conclusions) with critical analysis and evaluation. So readable it couldn't be put down. ▪ Good flow and very clear writing style. ▪ Excellent use of presentation techniques (diagrams, tables, pictures, etc.). ▪ Relates to wider issues in field of study. ▪ Publishable in a major conference or journal.
85% (excellent)	<ul style="list-style-type: none"> ▪ Very thorough understanding of key concepts and of the distinguishing features and trends within the field of study. ▪ Overview of the field used as a basis for independent judgement. ▪ Clearly states objectives, and the whole report relates to achieving those. ▪ Clear structure (introduction, sections, conclusions) with critical analysis and evaluation. Stimulates interest in the reader. ▪ Good flow and clear writing style. ▪ Excellent use of presentation techniques (diagrams, tables, pictures, etc.). ▪ Relates to wider issues in field of study. ▪ Publishable in a minor conference or journal.
75% (first class)	<ul style="list-style-type: none"> ▪ Thorough understanding of key concepts and of the distinguishing features and trends within the field of study. ▪ Overview of the field used as a basis for independent judgement. ▪ Clearly relates to title and stated aims. Omits the irrelevant. ▪ The objectives are distinctly ambitious but are rarely defeated. A clever solution is found. ▪ Clear structure (introduction, sections, conclusions) with critical analysis and evaluation. Stimulates interest in the reader. ▪ Good flow and clear writing style. ▪ Excellent use of presentation techniques (diagrams, tables, pictures, etc.). ▪ Relates to wider issues in field of study. ▪ Any artefact is of excellent quality.
65% (upper second class)	<ul style="list-style-type: none"> ▪ Good understanding of some but not necessarily all features of the field. ▪ Fluent use of concepts. ▪ Sound structure and good flow. Maintains interest. ▪ Addresses the topic. ▪ Links to wider issues in the field of study. ▪ Evidence of background reading and knowledge. ▪ Some critical evaluation. ▪ Any artefact is free of significant defects.

55% (lower second class)	<ul style="list-style-type: none"> ▪ Evidence of some understanding of the field or explanation of some issues in the field. ▪ Some use of concepts. ▪ Structured but bitty or sometimes unconnected. ▪ Descriptive without analytic purpose. ▪ A surface approach to literature reviewed. ▪ Does not stimulate reader's interest. ▪ Any artefact is of satisfactory quality.
45% (3rd class)	<ul style="list-style-type: none"> ▪ Grasp of basics. ▪ Descriptive - "surface" approach - little analysis - does not discuss topic. ▪ Limited understanding of relevance to the wider field. ▪ Failure to present the work in a context that the reader can understand. ▪ Any artefact works but has bugs.
35% (fail)	<ul style="list-style-type: none"> ▪ Descriptive with little or no analysis. ▪ Confused or wrong over theory and concepts. ▪ Little evidence of reading. ▪ Irrelevant and muddled. ▪ Any artefact does not work.
25% (fail)	<ul style="list-style-type: none"> ▪ Brief description but no analysis. ▪ Lots of errors of fact. ▪ No evidence of reading. ▪ Any artefact is substantially incomplete.
15% (fail)	<ul style="list-style-type: none"> ▪ Little description of relevance but may define the project area or state one issue relevant to the project. ▪ Structure and/or writing style make report difficult to read. ▪ A necessary artefact was not constructed.
5% (fail)	<ul style="list-style-type: none"> ▪ No substantive content but may state something about the project. ▪ No evidence of any work being done.
0%	<ul style="list-style-type: none"> ▪ Nothing submitted.

Coursework Submission Dates

Research Methods

Students will be expected to submit their reports by use of the online drop-box by 15:00 hrs GMT on the Friday of the 12th week after the beginning of the module. Dates will be posted on the Module homepage and on the 'Assessment' page of the site.

Project

Project submission will be carried out in a different way to the submission of the Research Methods report. Students have a year in which to complete their project, and within that year there are four possible submission dates. Students choose a preferred submission date at the start of their Project preparation. If students wish to move to a later submission date, this can be done in agreement with their project supervisor and account manager. More details on submission procedures will be provided on the module site.

Submission dates will be posted on the module homepage.

Coursework submissions will not be accepted unless they contain a cover sheet (available from the forms section of the 'MSc Strategic Business IT' site).

Important Submission Details

(As stated in the Academic Regulations – Examination and Assessment Regulations, AR.1.10 Version 3.3)

11. iv. Coursework submitted on or before the published submission date will be marked promptly and returned to students, with feedback within the prescribed time... (as detailed above).

v. Coursework submitted after the published submission date, but within two weeks of that date ... will be marked. The mark awarded will be limited to the unit pass mark, but the uncapped mark must also be shown on the coursework.

vi. Coursework submitted more than two weeks after the published submission date will be marked, but a mark of zero will be recorded on the student's record.

vii. The requirements... relating to feedback and prompt return of work (as detailed above) will not apply to work that is submitted late.

Please bear in mind that Extenuating Circumstances as detailed below may affect these marks when taken to the UAB.

Procedure for the release of marks and feedback

Provisional marks for the Research Methods module will be made available to students within four weeks of the submission deadline. These provisional marks will be subject to change and/or moderation until they are finally determined by the UAB. Students will be informed of any changes to their mark after the UAB has taken place. More details will be posted on each unit's noticeboard nearer the time.

Deferrals and Referrals

If, at your first attempt at a unit, you do not get an overall mark of 40%, then you will not have

passed the unit. In educational language you will not have met the learning objectives of that unit! The Unit Assessment Board that looks at your results will then make one of a number of decisions concerning your case. If this is the first time that you have taken the unit the most likely decision is that you will be given a referral (in University of Portsmouth terminology this is now called a Limited Repeat Assessment or LRA for short). You will find more details about referrals or LRAs in another FAQ below.

If you are being considered after doing a LRA which you have not passed, the UAB will set your result to a Fail for that unit. You can then be asked to undertake a Repeat Assessment by the Board of Examiners, see FAQs below for more detail.

Referrals or Limited Repeat Assessments (LRA)?

A referral or LRA occurs when you have failed to meet the learning outcomes of a unit that you have studied. The Unit Assessment Board will specify a piece of work or pieces of work that you must undertake in order to pass the unit, that is to meet the learning outcomes. The most common cases are where the coursework and examination for a unit are assessing different learning outcomes and you have, for example, not passed the coursework, then you will be asked to do another coursework. Sometimes, a completely new piece of work will be set which is set specifically for referral or LRA students and assesses all of the learning outcomes of the unit.

You will be sent details of exactly what you are required to do for your referral or LRA and also, and this is most important, the time by which it must be achieved. If you do not successfully pass the LRA assessment in the timescale laid down then you will have lost your referral or LRA and will then have to undertake a Repeat Assessment (see FAQ below). If you have been given a referral (LRA) in a unit, to pass that unit you must get a minimum of 40% in the referral assessment that is set for you. Once you have done that, the Unit Assessment Board will give you credit for that unit. However, the mark that you gained for that unit, (and the mark that will be used to contribute towards your final degree) will only be 40% no matter how well you did in the assessment.

Repeat Assessments (RA)/Resits

A Repeat Assessment as the University of Portsmouth calls it, is when you are required to redo all the assessments of a unit. Students who are given a Repeat Assessment are normally advised to attend the unit, that is to join the next official run of the unit and to study it with that group of students. However, there is no requirement for the student to do this, all that is required is that the complete set of assessments are submitted. The assessments will be marked in the normal way and an overall mark for the unit calculated in the normal way, that is by combining both coursework and examination marks. If the overall mark for the unit is 40% or higher then you will have passed your repeat assessment. The Unit Assessment Board will then award the credit points for that unit. However, the mark that is given for that unit, and the mark therefore that is used in the calculation of your degree, will only be 40%.

Deferrals

A deferral occurs when you have failed to meet the learning outcomes of a unit that you have studied but have submitted an ECF. The Unit Assessment Board will specify a piece of work or pieces of work that you must undertake in order to pass the unit, that is to meet the learning outcomes. Unlike a referral where your mark is capped at 40%, your deferral mark will not be capped.

You will be sent details of exactly what you are required to do for your deferral and also, and this is most important, the time by which it must be achieved. If you do not successfully pass

the deferral assessment in the timescale laid down then you will have lost your deferral and you will then have to undertake a Limited Repeat Assessment (see FAQ above). Please refer to the Academic Regulations for more details.

The Appeal Process

If you have any queries relating to the assigned mark or if there has been some error in the marking, you should approach the relevant Module facilitator and ask for the work to be re-marked. This should be done in writing within 2 weeks of the date that the assessment was made available for return. If you feel after re-marking that the mark is still not a fair reflection of the work submitted then you should further query the mark, giving reasons, in writing to the Head of Department within 2 weeks of the re-marked work being returned to you.

If, after exhausting all these procedures within the department, you wish to take the matter further you may formally appeal - see below. It may be a good idea at this stage, or even before, to contact your Account Manager. In the first instance, however, it is usually best to contact the Module facilitator for some informal feedback.

Formal Appeals

To mount an appeal you should first contact the chairman of the Board of Examiners who may be able to resolve the difficulty. Failing this, an appeal should be made, in writing, to the Academic Registrar within 14 days of the date of the official notification of the academic decision. However, the only grounds, which must be supported by evidence, on which an appeal will be considered are:

- The Board of Examiners was unaware of some significant factor that may have affected the academic decision.
- That procedures for the conduct of the assessment were not properly followed.

Awards of MSc

If you have completed the PgD and top up you will receive a Master of Science Degree. However, you may be eligible to receive an award with Merit or Distinction if you meet the criteria as outlined below. Only the units you have studied as part of the top up will be considered in the grading of the MSc. The grade boundaries are as follows:

Distinction: 70% +

Merit: 60% - 69%

Pass: 40% - 59%

A student will achieve these grades for the overall MSc if he/she achieves the above grades in both units (Research Methods and Project). That is, for a student to achieve a distinction overall in the MSc, he/she must achieve above 70% in each unit (not an average over both units), and this must be achieved at the first attempt.

Extenuating circumstances

If you experience circumstances relating to your health and/or personal life which are of a sufficiently serious nature to result in **either** you being unable to participate, complete or submit an assessment on time or your performance in an assessment being significantly affected then it may be appropriate for you to complete an extenuating circumstances form (ECF). The form can be downloaded from the course website or emailed to you by your account manager. Consult your account manager or module facilitator on how to complete the form.

At the end of each semester a panel of senior academics will convene to review these claims and determine whether the extenuating circumstance is valid (accepted) or invalid (not accepted).

Students must be prepared to complete missed or incomplete examinations or coursework, even though their studies may have been disrupted through no fault of their own, e.g. illness. For more details consult the 'Extenuating Circumstances Guidelines for Students' (link on 'MSc Strategic Business IT' site).

Welcome

Studying for a University qualification by distance learning is a major commitment. The University of Portsmouth has delivered distance learning courses for many years, so we have a lot of experience to help you reach your goals.

At the University we provide study opportunities of the highest quality at undergraduate, postgraduate and research level.

This course aims to provide you with skills for life as well as learning. The importance that we place on this reflects the concern of future employers that you should develop team and individual skills as well as academic knowledge. Our success in achieving this, with our recognised quality standards and excellent contacts with employers in the UK and overseas, helps explain the success of our graduates in gaining employment and advancing rapidly in their chosen careers. Finally, we are a growing, dynamic, multi-cultural community in which each individual student is assured of respect and privacy, but is able to gain support and advice where it is needed.

Dr. Simon Claridge
Dean of the Faculty of Technology

Course Introduction

This programme is a follow-up to the NCC's Postgraduate Diploma in Strategic Business IT, which is designed to build on individuals' existing IT skills and develop the skills and knowledge to undertake IT management responsibilities and senior roles. It will also provide students with an understanding of the strategic issues associated with businesses operating within the IT environment.

Delivery Model

The programme is delivered as follows:

Activity

Induction Course

Research Methods Taught Module and Project Module

Project Preparation (under staff supervision)

Duration

1 week

12 weeks 3m

13 weeks minimum 3m + 1w

The two units run in a semi-parallel mode as there are several key areas of overlap between them that would benefit from this right from the start. Students are encouraged to work on their project idea and as a mechanism for gaining facility in research ideas.

The Modules

A module is a learning component of a complete study plan covering a particular subject area. Please note that here at the University modules are called units. For this course we have changed most documentation to call them modules but please bear in mind that they both mean the same thing.

Credit Points - every completed module of a study plan is signalled by the award of credit points; in this case 15 credits for the Research Methods module and 45 credits for the Project module. In order to be eligible for a Masters award you must have acquired 180 credit points from the modules that you have studied. (In this case you already have 120 credit points acquired from the postgraduate diploma).

The Module specifications can be found by following the relevant link on the 'MSc Strategic Business IT' WebCT homepage.

Programme Structure

Week 1	Induction	
Week 2	Research Methods and Project Units	Lesson 1
Week 3		
Week 4	Lesson 2	
Week 5		
Week 6	Lesson 3	
Week 7		
Week 8	Lesson 4	
Week 9		
Week 10	Lesson 5	
Week 11		
Week 12	Lesson 6	
Week 13		
Weeks 14 -	Project Preparation	

Learning Model

All Modules will have an appropriate learning strategy. There are many views on how high quality learning can be achieved. However, there does seem to be good evidence to support the following learning model:

المشكلة
المشاكل
Problem centred - in that the learning is guided by a problem-solving outlook.

المثابرة
Perseverance - in that students require, for high quality learning, consistent and directed effort, guided by the facilitator.

الممارسة
Practice - is needed if true learning is to be achieved. This will be enabled by means of discovery sections in each on-line lesson.

التدريج
Progressive - in that the lessons are designed to build complex ideas from simple ones.

Private - in the sense that there is no need to teach every element of a particular knowledge domain, rather the facilitator should guide the student and only intervene when genuinely difficult ideas/materials are involved.

Public - or group learning because there is great value in learning in groups where we can exchange ideas, learn to be open-minded and build learning communities. This is facilitated by asynchronous on-line discussion and synchronous chat rooms.

The overall philosophy of any successful on-line learning strategy is to place the learner at the centre of a network of support structures and activities. Utilizing both synchronous and asynchronous collaborations with fellow learners as well as facilitators, and drawing upon the potential of the Internet to deliver information at any time to any place, the learner is empowered to structure and control their learning in a way that is uniquely suitable to them.

Delivery Method

This course is made up of 3 components:

Online Course Material – lesson content is accessible online through WebCT.

Textbooks – within the lesson content, there are references to the textbooks which are required for the Module/s. Students are expected to allocate time in their own schedule to complete the reading for particular lesson/s.

Communication – communication is carried out by the use of asynchronous discussion boards and synchronous chat rooms.

Asynchronous communication - Students are set discussion questions every week and are expected to review the discussion boards every other day and post comments.

Synchronous communication - Every week a chat session is held where the facilitator poses a question to all those that can attend and students can discuss the question with facilitator support. (The chat session is very much like a taught seminar/tutorial held online.)

More details on how to access the Learning site and participate in online communication can be found in the **Website Guide**.

Learning Materials

It is a prerequisite of this course that every student must purchase their own copies of the recommended textbooks for these two modules, which are as follows:

Research Methods module

Robson, W., (1997), *Strategic Management & Information Systems*, FT Prentice Hall. ISBN: 0 273 61591 2

Saunders, M. et al, (2002), *Research Methods for Business Students*, 3e, FT Prentice Hall. ISBN: 0 273 6580 4 2

Triola, M. F. 2003. *Elementary Statistics Using Excel*, 2nd edn, Addison-Wesley

Project module

Dawson, C. W., (1999), *The Essence of Computing Projects: A Student's Guide*, Prentice Hall. ISBN: 0 130 21972 X

Salkind, N. J., (2003), *Exploring Research*, 5th ed, Prentice Hall. ISBN: 0130983527

Study Hours

Module 1: Research Methods

Directed self study and contribution to discussion boards 96 hours (16 hours/week)

Contribution to chat rooms 6 hours (1 hour/week)

Module 2: Project

(Taught course)

Directed self study and contribution to discussion boards 80 hours (16 hours/week)

Contribution to chat rooms 5 hours (1 hour/week)

Staff Roles and Contact Details

There are a number of staff who work together to run your course and provide support. The following outlines the various roles. Contact details can be found on any of the module sites.

Facilitator 1

Facilitators are assigned to each module and provide academic support. They will review the discussion boards daily, conduct the chat sessions every week and can be contacted by the WebCT email with regards to any module queries. Your facilitator will also mark your assessments and provide feedback on them.

We will endeavour to answer your queries within 48 hours of receipt during University Office Hours as below.

Account Manager 2

Your account manager can deal with any non-academic queries you may have and can provide general course information. If you have a technical problem, you will need to contact the Account Manager as well and they will be able to advise you on a solution. They can be contacted by use of the Account Manager area of the discussion board and by email within WebCT. For technical queries which mean that WebCT can not be accessed please email anna.caudrey@port.ac.uk or telephone +44(0)23 9284 3102.

We will endeavour to answer your queries within 48 hours of receipt during University Office Hours as below.

Project Supervisor 3

As well as having a facilitator for the project module, you will also be assigned a project supervisor. Their role is to assist you and guide you through the development of your project and act as academic support for this part of the course.

Office Hours

Monday to Thursday 08:30 – 17:15 GMT

Friday 08:30 – 16:15 GMT

Data Driven Research Methodology

- No clear research hypothesis at the start of the research
- But significant amounts of data available
- No clear idea of which statistical/analytical methods to use
- Assumption that somewhere in the data there is knowledge to be discovered ('knowledge discovery in data' – KDD)
- Differs from data mining in that no clear outcomes/categories exist in the data
- The task is to find natural groupings in the data that can be used to generate a research hypothesis for further testing through traditional research methods

1

'Classical research methodology'

- Understand the research problem
 - review previous work (literature review) in the domain
 - summarise problems with existing work
 - formulate research statement
- Identify methods to be adopted for analysis
 - propose specific research hypotheses
 - identify data collection methods
 - identify statistical/analytical methods for determining truth or falsity of hypotheses
- Collect data and analyse using the methods specified above
- Analyse results against hypotheses and interpret the results
- Conclude with hypotheses for further testing

2

Collecting data

- The PQ administered as post-consultation (“exit”) survey with intention of securing at least 60 fully completed questionnaires per doctor
- Contributing volunteer doctors invited to identify and supply the names and contact details (work address, telephone, e-mail, relationship to the contributing doctor) of up to 20 colleagues, approximately half of whom should be medical peers, the other half being drawn from a variety of individuals whom the doctor judged might have had some insight into his/her medical practice in its widest sense.

Minimum		1	1	1	1	1	1	1
Maximum		5	5	5	5	5	5	5

Skewness: A measure of the asymmetry of a distribution. The normal distribution is symmetric, and has a skewness value of zero. A distribution with a significant positive skewness has a long right tail. A distribution with a significant negative skewness has a long left tail. As a rough guide, a skewness value more than twice its standard error is taken to indicate a departure from symmetry.

Kurtosis: A measure of the extent to which observations cluster around a central point. For a normal distribution, the value of the kurtosis statistic is 0. Positive kurtosis indicates that the observations cluster more and have longer tails than those in the normal distribution and negative kurtosis indicates the observations cluster less and have shorter tails.

Interim report on main study

PQ: average score across the seven professionalism items is 4.81 with average standard deviation of 0.14 for the 5910 patient responses for 152 doctors.

PQ: Cronbach alpha 0.93, inter-rater agreement 0.69

CQ: average score across the 14 professionalism items is 4.69 with average standard deviation of 0.6 for the 2763 colleague responses for 195 doctors.

CQ: Cronbach alpha 0.91, inter-rater agreement 0.42

Therefore, both questionnaires are highly reliable with strong inter-rater agreement

Second level analysis for interim study

Using a minimum number of 8 colleague responses and 12 patient responses resulted in 83 doctors with an average of 14 colleague responses and 39 patient responses.

The average across all seven aggregated PQ items was 4.83 and all 14 CQ items 4.69 which, when combined, resulted in an overall mean of means of 4.74.

Interim study confirms findings of several previous studies that data is highly skewed towards the top end of scale, with small standard deviations.

The F tests should be used only for descriptive purposes because the clusters have been chosen to maximize the differences among cases in different clusters. The observed significance levels are not corrected for this and thus cannot be interpreted as tests of the hypothesis that the cluster means are equal.

If there is no difference in the means of these items, the between-cluster variance will be approximately equal to the within-cluster variance and the F test value will be close to 1.

However, when the means differ significantly, the between-cluster variance will be much larger than the within-cluster variance and the F test value will be significantly greater than 1.

Hence CQ 12, CQ 3, CQ 11, CQ 13 are the most important of the colleague items

PQ 3d, PQ 3c, PQ 3g are the most important patient items

This information can be used to generate new hypotheses for further empirical test

13

Conclusion

Research methodology can be both 'top-down' as well as 'bottom-up', and can be iterative

Data driven methodology useful for identifying hypotheses for further empirical test

Useful for generating models that fit the data

Commercial advantages of KDD and data driven methods still not fully exploited by organisations storing huge amounts of archived data

'There is gold in them there hills...' that can inform business strategy and commercial exploitation

14

Introduction

Regulation of the UK medical profession is highly topical, following the publication of Fifth Report of the Shipman Inquiry and various responses and reports including, for instance, the recent Royal College of General Practitioners' report* and the CMO's *Good Doctors, Safer Doctors* consultation paper.[†] It is not currently clear whether there will be a re-licensing process based on a revised NHS appraisal system and a relevant medical Royal College re-certification processes for each doctor. There are a number of open questions concerning not only how to assess doctors' skills and competencies but also what to do with the data in terms of identifying doctors who may require further scrutiny.

There is growing interest in the UK and internationally in the role of peer assessment and patient feedback for the purpose of appraisal, revalidation and clinical governance.^{3,2} Several well-established peer and colleague assessment questionnaires now exist, including 'Professional Associate Rating' (PAR)³ and 'Peer review evaluation form' (PREF).⁴ The Alberta 'Peer Assessment Questionnaire'⁵ has evolved into the Medical Colleague Assessment Questionnaire (MCAQ) and the Co-worker Assessment Questionnaire (CWAQ).^{**} MCAQ contains 31 statements about physician practices for five attributes: clinical competency, psychosocial management of patients, patient interaction, professional self-management, and consultation communication, while CWAQ contains 17 statements about physician practices for three attributes: patient interaction, co-worker collegiality and co-worker communication. SPRAT (Sheffield peer assessment tool)⁶ is a recent UK addition designed to assess the components of trainee paediatricians. The questionnaire consists of 24 items covering: good clinical care; maintaining good medical practice; teaching and training, assessing and appraising; relationships with patients; and working with colleagues.

With regard to patients, the Alberta programme developed the patient assessment questionnaires (PAQ) that contained 40 statements about physicians' practices for 7 attributes: patient interaction, phone communication, information for patients, personal communication, office staff, physical office and appointments.^{††} GPAQ (General Practice Assessment Questionnaire) is a recent revision to GPAS (General Practice Assessment Survey)⁷ developed at the National Primary Care Research and Development Centre in Manchester and uses questions on access, inter-personal aspects of care and continuity of care as well as other aspects of quality not covered elsewhere in the 2003 GP contract. There is also a significant body of work on patient-based questionnaires, principally in

Table 1: Structure of the GMC patient and colleague questionnaires

Patient and Colleague Questionnaires – Questionnaire Structure		
Core domains	PQ Number of items	CQ Number of items
Introduction/explanation	+	+
Reason for attendance	2	-
Core questions on professionalism	7	14
Global assessments	3	4
Previous experience of this doctor	1	-
Demographics/ethnicity	3	3
Free text	+	+
Professional role and frequency of contact with indexed doctor	-	2
Total	16	23

For the core questions on professionalism 5-point Likert scale items were used (poor, less than satisfactory, satisfactory, good, very good) and, for the global assessment, a combination of Likert scales and binary (yes/no) items. The results reported here focus solely on the seven professionalism items of PQ and ten of CQ. The seven PQ items on professionalism address politeness, making the patient feel at ease, listening, assessing medical condition, explaining the medical condition, patient involvement in decision making and arranging treatment. The 14 CQ professionalism items address clinical knowledge, diagnosis, clinical decision making, treatment, prescribing, medical record keeping, working within limitations, keeping knowledge and skills up to date, self-reflection, teaching, supervising, patient commitment, communication with patients and relatives, and working with colleagues.

The PQ was administered as a post-consultation (“exit”) survey with the intention of securing at least 60 fully completed questionnaires. Contributing volunteer doctors were invited to identify and supply the names and contact details of up to 20 colleagues, who were approached directly by email and invited to complete a web-based, online CQ to assess the performance of the (named) doctor. Colleagues were assured that the index doctor was contributing to the study on a voluntary basis and that the doctor was not the subject of any competence, health, or disciplinary investigation. Data collection with a national cohort of doctors is on-going and but sufficient colleague and patient data for 83 doctors from around the UK now exists for an interim analysis to be made here.

Collection and management of data

All questionnaire data were cleaned during the data entry process, with missing data clearly identified and text comments stripped of any patient or doctor identifiers. Missing data were coded as such, rather than being imputed. A 10% random sample of PQ and CQ returns were double entered to examine the magnitude of data entry error (the observed rates were negligible).

Analysis

Item-internal consistency was examined using mean scores, standard deviations and Pearson correlation between the item and any scale to which it was assigned. Internal consistency reliability was examined by calculating Cronbach’s alpha and interclass correlation coefficient analysis (ICC – a measure between -1 and +1) to check on inter-

provides, for each doctor, a summary of how often their aggregated mean scores for the 21 items fell above or below the cohort means for those items and how many times they came bottom or top of their group for these 21 items. Cluster analysis of these 83 doctors (Figure 1) using all 21 aggregated items revealed two major clusters.

Discussion

Assessment of doctors consists of two phases: how to collect the data, and what to do with it. With regard to the first phase, preliminary results indicate that the GMC questionnaires are highly reliable and lead to high inter-rater agreement. Factor analysis of the patient questionnaire indicates no redundancy among the items (only one component was extracted), and similarly for the colleague questionnaire, although both these results are provisional until the full dataset is analysed. However, the use of just seven PQ items and 14 CQ items with 5-point Likert scales currently appears to be sufficient for obtaining highly reliable assessment data concerning professional aspects.

With regard to the second phase, while a measure of how a doctor's performance compares to the rest of the cohort can be gleaned from a comparison with cohort averages across items (Table 2), this does not take into account the magnitude of the variance. One or two 'rogue' responses from patients or colleagues, for instance, can lead to a doctor appearing to perform weakly by lowering the averages just below the mean.

Cluster analysis, however, takes the magnitude of variance into account (Figure 1). The tree reveals two major clusters: Doctors 49, 59, 39, 80, 33, 25, 73 and 48 (bottom of diagram), and the rest. Doctor 49 with 20 below-average assessments and seven bottom performances (Table 2) is the 'worst performer' relative to all other doctors in the cohort. The cluster diagram also identifies doctors 59 (16 below average, 5 bottom), 39 (18,2), 80 (20,1), 33 (20,1), 25 (19,0), 73 (11,1) and 48 (16, 0) as falling in a separate cluster from all other doctors. At the other end of the clustering, doctor 38 was above average on 20 items and came top (or equal top) on six others. Doctors 44 (19, 4), 4 (20,3), 65 (19,7) and 15 (19,4), and all the other doctors down to Doctor 32 (16, 4) also performed well in comparison to the cohort, although the number of below average performances increases as we move down that cluster.

Limitations and strengths

No attempt has so far been made to relate the seven professionalism items on PQ with the 3 summative/global items on the same questionnaire, and similarly with the 14 professionalism items on CQ with the four summative/global items. Also, no attempt has been made to separate patient and colleague responses by the specialism or category of doctor to check for sub-cohort differences. Both will happen once all responses are received for the 500 or so doctors already recruited. While a very small number of doctors has been separated from the main cohort through cluster analysis, it must be stressed that the professional performance of all these doctors is satisfactory in absolute terms and that the great majority are obtaining aggregated scores in the 4-5 (good to very good) range.

Table 2: The total number of items for which each doctor falls either below (<) or above (>) the means for the cohort as a whole, and the number of items for which a doctor comes bottom or top (perhaps tied).

--	--

Thank you for your time and help

The following questions provide us only with general information about the range of people who have responded to this survey.
This information will not be used to identify you and will remain confidential.

19

Are you: Female ☐ Male ☐

20

Your age: _____

21

Your professional role (please tick only one box):

- 1 ☐ Doctor If you are a doctor, are you on a training grade? Yes ☐ No ☐
- 2 ☐ Registered Nurse 7 ☐ Pharmacist
- 3 ☐ Allied Healthcare Professional 8 ☐ Practice Manager
- 4 ☐ Midwife 9 ☐ Administrator
- 5 ☐ Health Visitor 10 ☐ Other (please specify): _____
- 6 ☐ Health Care Assistant

22

How recently were you familiar with this doctor's clinical practice?

- 1 ☐ Current colleague 2 ☐ Within the last 2 years
- 3 ☐ Between 2 and 5 years ago 4 ☐ Between 5 and 10 years ago 5 ☐ More than 10 years ago

23

During this period of your familiarity with this doctor's clinical practice, how often did you have contact with the doctor?

- 1 ☐ Most days 2 ☐ Weekly 3 ☐ Monthly 4 ☐ Less often

24

What is your ethnic group? Please tick one box from the following selection to indicate your cultural background. (We will use this information for this study only)

- 1 ☐ White British 7 ☐ Pakistani
- 2 ☐ White Irish 8 ☐ Bangladeshi
- 3 ☐ White and Black Caribbean 9 ☐ Caribbean
- 4 ☐ White and Black African 10 ☐ African
- 5 ☐ White and Asian 11 ☐ Chinese
- 6 ☐ Indian 12 ☐ Any other (please say which): _____

Please feel free to add any other comments you have about this doctor.

Thank you for your time and help

Patient Questionnaire for

The General Medical Council (GMC) is proposing that all doctors will have to show that they are up to date and fit to practise medicine. They have arranged a test study to see if feedback from questionnaires is an effective means of assessing the skills of a doctor.

Your doctor is NOT being investigated by the GMC but has willingly agreed to contribute to the study.

- The feedback you give may be used to improve future healthcare
- All information will be kept **confidential** to the study team
- The doctor will not see your answers, so please give honest feedback
- Please do not write your name on this survey

When giving your feedback, please only consider the consultation you have had today.

1 Which of the following best describes the reason you saw the doctor today?
(please tick all the boxes that apply)

- | | |
|--|--|
| 1 <input type="checkbox"/> To ask for advice | 5 <input type="checkbox"/> Due to an ongoing problem |
| 2 <input type="checkbox"/> For treatment (including prescriptions) | 6 <input type="checkbox"/> Due to one off / isolated problem |
| 3 <input type="checkbox"/> For a routine check | 7 <input type="checkbox"/> Other (please give details) |
| 4 <input type="checkbox"/> Accompanying someone else | |

2 On a scale of 1 to 5, how important to your health and well-being was your reason for visiting the doctor today?

Not very important 1 ☐ 2 ☐ 3 ☐ 4 ☐ 5 ☐ Very important

3 Please rate how good your doctor was today at each of the following by ticking <u>one</u> box along each line.		Poor	Less than Satisfactory	Satisfactory	Good	Very Good	Does not apply
a	Being polite						
b	Making you feel at ease in his / her presence	1 <input type="checkbox"/>	2 <input type="checkbox"/>	3 <input type="checkbox"/>	4 <input type="checkbox"/>	5 <input type="checkbox"/>	6 <input type="checkbox"/>
c	Listening to you	1 <input type="checkbox"/>	2 <input type="checkbox"/>	3 <input type="checkbox"/>	4 <input type="checkbox"/>	5 <input type="checkbox"/>	6 <input type="checkbox"/>

e	Explaining your condition and treatment	1 <input type="checkbox"/>	2 <input type="checkbox"/>	3 <input type="checkbox"/>	4 <input type="checkbox"/>	5 <input type="checkbox"/>	6 <input type="checkbox"/>
f		1 <input type="checkbox"/>	2 <input type="checkbox"/>	3 <input type="checkbox"/>	4 <input type="checkbox"/>	5 <input type="checkbox"/>	6 <input type="checkbox"/>
g	Providing or arranging treatment for you	1 <input type="checkbox"/>	2 <input type="checkbox"/>	3 <input type="checkbox"/>	4 <input type="checkbox"/>	5 <input type="checkbox"/>	6 <input type="checkbox"/>

Figure 1: Cluster analysis (dendrogram) of all 83 doctors.

Conclusion

It is still not clear how patient and colleague responses will feed into any revalidation process based on appraisal or other CPD processes and possible clinical tests. Nevertheless, the cluster analysis results indicate that it is possible to take a 'profile-wide' approach to identifying doctors who may require further scrutiny rather than an item-by-item approach. Also, the reliability results indicate that patient and colleague data, aggregated by individual doctor, can help generate profiles for such identification.

rater agreement. Cluster analysis was used on aggregated data for each doctor groups maximally distinct for the purposes of satisfactory and unsatisfactory practice.

Cluster analysis explores and mines data with the purpose of categorising different samples into groups such that the degree of association between two samples is maximal (their variance is minimal) if they belong to the same group and minimal (their variance is maximal) otherwise. In hierarchical cluster analysis, each object is initially assigned to its own cluster, followed by an iterative process whereby the two most similar clusters form a new cluster until one overall cluster results. The output is in the form of a taxonomy or hierarchical tree. Samples of increasing dissimilarity are aggregated at various levels of the tree using a rescaled metric (typically ranging from 1-25). A number of different distance measures are used to identify similarity/dissimilarity of objects. In the hierarchical cluster analysis results reported below, squared Euclidean distance (D) is adopted whereby the squared and summed differences across all 21 aggregated item

scores are calculated according to the formula: $D = \sum_{i=1}^q |S_i - S'_i|^2$, where q is the number

of questionnaire items, S and S' are two different doctors, and every doctor is compared pair-wise with every other doctor so that a 'similarity/dissimilarity' matrix results. A variety of methods also exist for combining clusters. The method adopted here (unweighted pair-group method using centroid average) calculates the distance between two clusters as the difference between their centroids, where a centroid is the average point in the multidimensional space formed by all 21 items. All analysis was undertaken with SPSS v12.

Results

For PQ (unaggregated by doctor) the average score across the seven professionalism items was 4.81 with average standard deviation of about 0.5 for the 5910 patient responses for 152 doctors. About 0.8% of all responses fell in the adverse categories (poor, less than satisfactory). Internal reliability via Cronbach alpha was 0.93 and the ICC 0.68, with 95% confidence interval 0.669 to 0.689. There were strong inter-item correlations (minimum 0.62, maximum 0.79, average 0.69) as well as strong item-scale correlations (minimum 0.78, maximum 0.81). When the seven items were summed to form a scale, the mean was 33.69/35 with standard deviation 2.98.

For CQ the average score across the 14 professionalism items was 4.69 with average standard deviation of 0.6 for the 2763 colleague responses for 195 doctors. About 0.5% of all responses fell in the adverse categories. Cronbach alpha was 0.91 and ICC 0.42, with 95% confidence interval of 0.401 to 0.445. Inter-item correlations ranged from 0.269 to 0.733 with an average of 0.435, and item-total correlations ranged from 0.52 to 0.71. The scale average was 65.72/70 with standard deviation 5.13.

The patient and colleague datasets were then aggregated by doctor for second level analysis. Using a minimum number of 8 colleague responses and 12 patient responses resulted in 83 doctors with an average of 14 colleague responses and 39 patient responses. The average across all seven aggregated PQ items was 4.83 and all 14 CQ items 4.69 which, when combined, resulted in an overall mean of means of 4.74. Table 2

the areas of family perception of care and patient perception of care, such as FAMCARE⁸ and the Palliative Outcome Scale (POS).⁹ In none of these studies is any systematic attempt made to aggregate information from colleagues and patients on individual doctors to provide an overall 360° colleague and patient-based view of specific doctors and other health professionals.

The Medical Council of New Zealand is subject to the Health Practitioners Competence Assurance Act (HPCAA) 2003.¹⁰ Each physician applies annually for a practising certificate and must declare their fitness to practise and participation in continuing professional development (CPD). If specific CPD requirements are not met, the physician is required to undergo evaluation based on the Alberta programme, entailing 360° feedback from 16 colleagues, 10 patients and self-assessment. A score of two standard deviations below the mean score will result in a suggestion from the Council that specific education in the relevant area is incorporated into the doctor's CPD for the following year. A score three standard deviations below the mean score will result in a requirement by the Council to incorporate education in the relevant area of the next year's CPD.¹¹

The use of standard deviations assumes the distribution of data is normal around the mean. However, a number of research studies, including that described here, indicate that colleague and patient data is highly skewed towards the top end (excellent/very good) of the Likert scale. Sometimes even one standard deviation from the mean can result in a score above the maximum possible (e.g. mean of 4.85 with standard deviation of ± 0.2 on a scale 1-5). Also, falling three standard deviations below the mean may result in a doctor still obtaining a score that means 'good' (e.g. average $4.85 - 3 \times 0.2 = 4.25$). If the questionnaires are reliable, normalisation procedures to re-distribute the data may not be justified.

The aim of the paper is to introduce an additional technique for identifying, on the basis of aggregated patient and colleague feedback, the small number of doctors who may require further scrutiny without the need to normalise the data or assume the data is normally distributed.

Methods

Setting and design

The design and presentation of questionnaires used in this study were based on instruments developed by the GMC's Revalidation Technical Group. The questionnaires themselves have at their heart core questions addressing the seven domains of "good medical practice", a series of policy statements produced by the GMC outlining and defining key areas of professional performance for doctors. The structure of the two questionnaires is described in Table 1.

⁸ 'Maintaining licensure – ensuring doctors competent and fit to practice in New Zealand', P. Barham and S. Ineson. Available from <http://www.mcnz.org.nz/portals/0/competence/PepPosterabstract%20-%20Sept%202005.pdf>.

Cluster analysis for identifying doctors for possible further scrutiny using aggregated patient and colleague data from pilot GMC questionnaires

Abstract¹

Objective To identify statistical methods for identifying doctors who may require further scrutiny as part of any revalidation exercise concerning re-licensing and fitness to practice, and to test the reliability of questionnaires currently being piloted by the GMC for assessing the performance of doctors through patient and colleague feedback.

Design Pilot study consisting of issuing separate questionnaires to patients and colleagues of individual doctors, determining the reliability and validity of these questionnaires and aggregating the judgements for a second level assessment of each doctor.

Setting Several practices throughout the UK.

Participants 500+ doctors have been recruited and, while the study is still in progress, the results here are for 83 doctors who had sufficiently complete patient and colleague responses.

Main outcome measures Separation of doctors whose patient and colleague responses on key professional items locate them as possible outliers in the cohort.

Results Patient and colleague responses indicate great satisfaction with the performance of doctors for the most part. Specific doctors were identified as possible outliers through comparisons of profiles and hierarchical cluster analysis.

Conclusions Cluster analysis provides a useful, additional mechanism for in identifying doctors who may require further scrutiny. GMC patient and colleague questionnaires can be used as one component of performance assessment.²

Cluster analysis to find structure in data

The term cluster analysis (first used by Tryon in 1939!) encompasses a number of different algorithms and methods for grouping objects of similar kind into respective categories.

A general question facing researchers is how to organize observed data into meaningful structures, that is, to develop taxonomies.

Cluster analysis is an exploratory data analysis tool which aims at sorting different objects into groups in a way that the degree of association between two objects is maximal if they belong to the same group and minimal otherwise.

Cluster analysis can be used to discover structures in data without providing an explanation/interpretation. In other words, cluster analysis simply discovers structures in data without explaining why they exist.

11

The tree reveals two major clusters: Doctors 49, 59, 39, 80, 33, 25, 73 and 48 (bottom of diagram), and the rest. Doctor 49 with 20 below-average assessments and seven bottom performances is the 'worst performer' relative to all other doctors in the cohort. The cluster diagram also identifies doctors 59 (16 below average, 5 bottom), 39 (18,2), 80 (20,1), 33 (20,1), 25 (19,0), 73 (11,1) and 48 (16, 0) as falling in a separate cluster from all other doctors. At the other end of the clustering, doctor 38 was above average on 20 items and came top (or equal top) on six others. Doctors 44 (19, 4), 4 (20,3), 65 (19,7) and 15 (19,4), and all the other doctors down to Doctor 32 (16, 4) also performed well in comparison to the cohort, although the number of below average performances increases as we move down that cluster.

Skewness: A measure of the asymmetry of a distribution. The normal distribution is symmetric, and has a skewness value of zero. A distribution with a significant positive skewness has a long right tail. A distribution with a significant negative skewness has a long left tail. As a rough guide, a skewness value more than twice its standard error is taken to indicate a departure from symmetry.

Kurtosis: A measure of the extent to which observations cluster around a central point. For a normal distribution, the value of the kurtosis statistic is 0. Positive kurtosis indicates that the observations cluster more and have longer tails than those in the normal distribution and negative kurtosis indicates the observations cluster less and have shorter tails.

Reliability of questionnaires?

- Cronbach's Alpha is a statistic that is used to estimate the reliability of a test
- Cronbach's alpha assesses the reliability of a rating summarizing a group of test or survey answers which measure some underlying factor (e.g., some attribute of the test-taker). A score is computed from each test item and the overall rating, called a 'scale' is defined by the sum of these scores over all the test items. Then reliability is defined to be the square of the correlation between the measured scale and the underlying factor the scale was supposed to measure.
- Varies from 0.0 to 1.0, with scores of 0.8 and above indicating strong reliability of the questionnaires

‘Classical’ data driven methodology

- start with the data and understand it
- try out different statistical methods to see which one or more produces ‘interesting’ results
- may need to reduce the number of variables using some a priori assumptions as to which are most relevant (‘feature selection’)
- identify models that ‘fit the data’
- may need to use cross-validation techniques (leaving out some samples for testing the generalisability of the model)
- often called ‘reverse engineering’
- analyse model to derive hypotheses for classical, hypothesis-driven research

CFEP - UK SURVEYS
Helping People Make a Difference

PENINSULA⁴
MEDICAL SCHOOL
UNIVERSITY OF EXETER & PLYMOUTH

The Master's programme involves two units of study: Research Methods followed by a full Project. The full assessment plan for the Master's program can be found in Workbook 1 of the workbook pack – you must ensure that you are familiar with this plan which essentially describes 3 assessment artifacts – 1a, 1b, 2 and 3.

ASSESSMENT 1a. PJ.NCC – PROJECT SPECIFICATION

The specification developed in this part of the course is regarded as part of the Project Unit and allows you to gain a maximum of 10% of your final project mark before the project begins. In addition, no student will be allowed to start the project until a specification is approved by the University. This specification is developed during the Research Methods unit and is carried out in two stages as described below.

Formatting Requirements - Formatting (if you depart from the spirit of these formatting instructions your work will NOT be marked)

File name is just your HEMIS No with contents as a single MS .doc document using A4 pages.

The font is to be Arial Narrow at 12 pt with 10 pt in diagrams and tables at 6 lines per inch.

The margins to be 2 cm - top, bottom, left and right.

Page header: 'Assessment 1a', Student Name, HEMIS No and Course name'

Page footer: page number in the form Page 1 of 5, 2 of 5 etc and your email address.

Penalties - Any penalty for exceeding the page limit for this work will be decided by the Research Methods tutor. Typically, there will one mark deducted for each page over the limit.

Restrictions - The appendix contains a list of project ideas. Normally, project ideas in the following areas may not be accepted: eBanking, eCommerce, mCommerce, eLearning, Web Site Strategies, Outsourcing, wireless technology and systems, PDA and mobility, simple HCI, Music Distribution or simple security. If you feel that you have a novel or new view on any of the above with a hint of originality then you should approach the Research Methods lecturer to seek his opinion before attempting to write a submission.

Students are reminded that the project must be new work and students are NOT permitted to use any project material that may have been used before on another course or for another purpose. If it is discovered that research material is being re-used it will result in immediate disciplinary action.

STAGE 1. GAINING TITLE/IDEA APPROVAL

There are two parts to this stage:

Personal Profile - You must immediately send your personal profile to the Research Methods lecturer in a WebCT email message (not an attachment). It should be no more than 200 words and must contain:

1. Your current job title,
2. Your company name and location (country where you work)
3. A description of the core work you do
4. A description of your special area of expertise
5. Your Strategic Business IT area or areas of interest relevant to MSc project selection

If you are unemployed then say what expertise you have in whatever area in place of a job description. The Research Methods lecturer will use this information to guide you when he receives your title submission. The profile may also be made available to the University panel that approved your final specification. Please note that no work will be reviewed until your profile is recorded in the records database by the Research Methods lecturer.

ASK for the project to Review & Keep a copy.

- b **Title Submission** - As soon as possible, select a title from the appendix of this document or find one of your own. To gain approval for that title from the Research Methods lecturer write a brief project outline in the format described below embedded in a WebCT email message (not an attachment). Approval may be gained at any time up to one week before the assessment 1a submission date and is worth up to 5% of the marks for Research Methods Unit (Assessment 2).

The topic MUST have an outcome that is in some way having a strategic outcome for it to be acceptable. Strategy in this sense means or implies a long term plan to gain the expected business value. Now the actual outcome may be expressed in all sorts of ways but it must have some relation to Strategic Business IT. Examples:

forms work procedure
it could be a policy framework dealing with IT security issues,
it could be a survey of some aspect of computer help desks that might improve the service
it could be a report on the effectiveness of a software tool and so on.

The whole idea is that the outcome from your project has some impact on the IT infrastructure itself or its use.

Title Approval Submission Format

(500 words)

The submission must not exceed 700 words using the 9 headings shown below. When constructing a submission you MUST expect to go backwards and forward over all the headings and carefully study all the relevant workbook sections. In assessing the submission the tutor will firstly look for consistency between all the headings (unfortunately, some students seem to take the view that each of the headings is a new question and therefore they need not ensure that as a whole the submission make sense). Secondly, that there is a clear strategic Business IT dimension. And lastly, the Basic Activity for Generating Data is clear and practical and leads to the data specification and Research Method.

1. **Title** - Construct a clear title in not more than 100 characters. Use Workbook 6 and the section on writing a title to help you do this.

2. **Topic Outline** - Give a short overview of your chosen topic area. Worksheet 1 of Workbook 5 may help you to prepare this section (not more than 100 words). Please remember, this is NOT a description of what you are going to do, it is a description of the topic area.

3. **Problem to Solve** - say what single significant IT or IT related problem you are trying to solve. (not more the 100 words)

4. **Theory** - try to say what your personal theory is about the situation that has led you to seek a particular solution to the problem you identified above. Use Workbook 6 and the section on theory to be certain you know what is expected here. (not more than 100 words)

5. **Research Question** - write a clear statement of the question you want to ask as a way of encapsulating the quest to resolve your problem theme. Use Workbook 6 and the section on writing a Research Question and the many examples there to help you do this. (not more than one sentence)

6. **Expected Form of Answer and its Strategic IT value** - be clear what form of answer you are expecting from your Research Question and that the form can actually be constructed from your primary data. Use Workbook 6 and the section on writing a Research Question paying particular attention to the examples given there on both question formulation and form of answer. Finally, try to show that obtaining an answer to your research question in the form that you have described will have a strategic business IT outcome that will be valued by business. You should not the form of answer you define here will be your MSc Project outcome in the project unit. (not more than 100 words)

↓

7. Basic Activity for Generating Data – what single key action will you take as a way of getting the data that you will need to answer your Research Question? This is a key section and you are advised to study all the examples in Workbook 6 so that you are confident you know what is expected here. If you are not clear here the whole specification and project will fail. (not more than 50 words).

8. List of Primary Data Items – give a selection of data that you will be looking for but it must be obvious that it is primary data and it could be used to generate the form of answer you expect and arises naturally out of your Basic Activity for Generating Data. Every project must be based on the collection, presentation and processing of primary data. Primary data means data that is original to you and did not exist as a collection before YOU collected it. You may in support of your work also use secondary data sources. (about 50 words).

9. Research Method - Give a brief outline plan and rationale of how you will locate and collect the data that you specified above using one of the methods outline in Workbook 7 (case studies, action research etc) to guide you in this. The method has to be practical, credible and suited to what it is you are doing. (not more than 100 words).

STAGE 2. WRITING THE SPECIFICATION

Once you have an approved title you are allowed to construct a full specification which you will later use to complete assessment 1b which is the final MSc full project. The submission date and drop box for the specification will be published by the Account Manager in the course schedule which may be found in WebCT under General Information and Forms. Your specification will be marked by the Research Methods lecturer and reviewed by a University committee for final approval. The complete specification is worth up to 10% of your Project marks in assessment 1b. If your specification is not approved by the University you will have another opportunity to try again in the next available cohort either with the same title or with a new title.

Specification Format

The specification must be written using the study style heading format shown in workbook 3. The specification must not exceed 6 A4 pages using the formatting rules stated earlier in the document.

Workbook 3 gives you detailed notes on what a project specification must contain and then offers you a worked example for guidance. You must expend considerable effort on researching the topic area as well as the selected Research Method and then reading and carefully studying the notes and workbooks. There is no short cut here and the standards are high and will never be compromised.

You are advised that the tutor is not permitted to read your specification before submission as it must be seen as entirely your own work since it is a formal assessment. However, the tutor will be happy to accept specific questions about any aspect of the specification construction.

Note.

There work done in this specification may be carried over into assessment 2 which covers a similar area but with some new sections. The expectation is that based on the feedback you get from assessment 1a you will be able to improve on many areas found in the specification and repeated in Assessment 2.

Appendix. Project Topic Ideas

Some ideas for final Projects and for use in this assessment – you don't have to select one of these they are just to give you a flavour of what you might look at. The list below was written as general ideas but they could always be applied to a particular situation as well.

No two students will be allowed to use exactly the same idea so it is important for you to get started before all the good ideas are selected and allocated.

1. The effect on Profitability of implementing an IT supported Asset management system
2. The effect of IT systems on company Policy
3. The effect of company Policy on IT procurement
4. How company policy drives IT system selection
5. High Quality IT systems increases worker commitment
6. Highly Integrated systems such as SAP increases worker commitment
7. Highly Integrated systems such as SAP increases worker stress
8. Reliance on private computer systems increases the costs of worker stress
9. How IT can help with Life Cycle logistics in asset Management systems
10. Life Cycle logistics in IT systems
11. How important is user acceptance in the utility associated with IT systems
12. Company policy on IT training affects user acceptance of IT system
13. The impact on worker productivity/morale of removing all personal systems
14. IT Project Management Practice could be improved by the Use of Emotional Intelligence
15. Configuration Management Software and large scale IT installations
16. System Development Life Cycles and their Role in project management Methodologies
17. The impact of Internet enabled systems on resource usage
18. Assess and justify the rational use of the ILS techniques on future IT projects
19. IT outcomes that may prove useful in justification of application of ILS
20. Appraise and judge problems that may be encountered in application of ILS
21. Recommend a corporate strategy with ILS as a core profit center
22. Cost-benefit analysis justifying resource application to achieve IT supportability objectives
23. How ILS is applied to IT acquisition programs and their relation to outside influences
24. Appraise and predict the consequences of inappropriate application of IT Systems
25. Research and define contemporary approaches for applying ILS during the acquisition IT
26. Techniques for costing IT support requirements
27. Possible cost-based processes as critical management tools with regard to IT
28. Analyse, plan, evaluate or report on an IT Project
29. Define the role of ILS in a commercial sector IT procurement programmes
30. Explain the implications of ILS usage in IT installations
31. Report on commercial applications of ILS techniques or philosophies
32. Report on capital investment in an ILS capability for a large corporate IT user
33. IT and Logistics Management
34. IT ethics and the economy/business
35. Technology & Warfare Strategies
36. eAuction - The Future of Procurement?
37. Teleworking and IT professionals
38. Mobile Business & Mobile Commerce
39. Mobile Internet Services – A business Tool
40. Enterprise permeability and the supply chain
41. Strategic role of IT in drug retailing in the Philippines/China etc
42. Impact of IT on international supply chain management
43. The impact of IT on global manufacturers
44. Mobile Communication Devices as a business tool
45. Internet and professional football/cricket/ etc
46. Highly integrated mobile computers system an their Impact on business Users
47. IT and Technology in Sport
48. Forensic IT
49. A business evaluation of Oracle
50. Telemedicine

51. Knowledge Management and its place IT planning/procurement/success etc
52. Web Services – The future for distributed systems (.NET and J2EE etc)
53. Computing Industry standards and their impact on business
54. Software Implementation strategies and their importance to business success
55. Software Maintenance – A company wide strategy for business support
56. Software risk management and its implication for IT strategies
57. IS needs must be matched to value in that IS systems can only be successful if there is a causal link to business success.
58. The impact of IT on financial service provision has been significant.
59. Micro-payment systems – the route to a cashless Society
60. Modern HRM systems have had a major impact on recruitment and retention of staff in large organizations.
61. Attempting to integrate all systems in a company is unwise (4)
62. Modern developments in integrated storage management (3) 1,5
63. Data life cycle management
64. The role of IT training in ensuring personal productivity
65. How new technologies related to location commerce might affect business policies
66. Leisure and simulation software and its possible role in training and development
67. Software Agent technology and its future role in mobile computing
68. Software agent technology and its role in improving search engine performance by profiling usage.
69. Software Agent Technology and its use in improving web applications
70. eMail - a Business Nightmare
71. Dealing with email enquires in large corporations
72. The role of eMail in a modern business Organization
73. eMail and ISPs
74. eMail and the personal user
75. eMail storage Systems and their impact on business
76. eMail currency and its impact on personal productivity
77. The impact of Spam on personal productivity
78. Then effects on business of organizations such as SPEWS in limiting SPAM
79. SPF (Sender Policy Framework) A Answer to SPAM
80. Phishing – a personal tragedy and a corporate nightmare?
81. VoIP and its effects on IT infrastructures
82. Skype and its use as a viable business communication tool
83. IT – How does it add Value to a business
84. The impact of the SPEWS protocols on dealing with unsolicited mail
85. Electronic Voting for Company Use
86. Content Management systems and their place in a Modern Organization (1) (1)
87. Software Failures are Management Failures?
88. Software Quality Assurance in Modern Development Environments and impact on Business
89. IT and Business Risk
90. IT hardware – A never ending Cost Centre
91. Storage Area Networks and their Impact on Business Policy (4)
92. Modern Societies Dependence on Electronic Storage
93. The Paperless Society – an impossible dream?
94. Document Management Strategies (2) (1)
95. Outsourcing Document Management (3)
96. Making better IT Investment Decisions (2) (2)
97. Strategic Issues in Document and Information Management
98. Developing a corporate Strategy for Document and Information Management
99. Document Management and support for Critical Business processes
100. Electronic Documents and Record Management (2)
101. The requirements gathering process is a major cause of project Management Failures
102. The role of IT as a strategic Business Resource
103. The Role of personal desktop applications in worker productivity – applications may include Word, photoshop etc)
104. IT/Computing standardization of systems and the impact on business success
105. IT/Computing standardization of systems and the impact on business policy
106. IT Infrastructure and Business Continuity Planning
107. Business Continuity Planning – A Replacement for IT Disaster Recover
108. The Role of IT Certification in Systems Operational Performance

109. The Role of IT Certification in terms of Strategic IT Development
110. The Role of IT Certification in Implementation Strategies
111. Electronic Document Management Systems and Business Success
112. IT Service Management and Business Success
113. IT Security Management and its Impact on Business success
114. IT Service Levels Agreement and Business Strategies
115. IT training issues and the disabled workforce
116. IT Collaboration Tools and Business Success (email, Intranets, shared files systems, desktops, user profiles etc)
117. Teleworkers and their Impact on IT security, business success, outsourcing etc.
118. IT Application and Organisational Change
119. The role of user training in Requirements gathering
120. The role of prototyping and user involvement in requirement gathering and proving
121. The role of emotional intelligence in IT user support
122. Implementation and training for BizTalk or Sharepoint Portal Server or Content Management Server etc
123. The role of BizTalk or Sharepoint Portal Server or Content Management Server in business success
124. Quality in IT services
125. SAN and Continuous Data Protection
126. Entry level SAN and the SMB/SME
127. Legacy Data and BI Tools sets
128. Leveraging Data and BI tools sets
129. RFID in a retailing Context
130. The Extended Enterprise (networks of suppliers, eProcurement etc)
131. Search Engines and business Efficiency
132. The IP enabled Economy
133. Optimisation of IT services (eg HP OpenView)
134. Hackers – Looking for fortune not fame
135. The adaptive Enterprise (that is growing IT as it is needed)
136. Migration Practices for Legacy Systems and Business Planning
137. IT Strategies and External Business Factors
138. Low cost search Engine optimisation and its business benefits
139. eGov in the Middle East
140. eBooks and Readers – their use by business
141. The Copper Conundrum – Twisted Pair products for 10G Ethernet
142. Performance and Power – GRID Computing (can the power available lead to increased business performance)
143. Anti-spyware – a business and personal necessity
144. Cyber spying
145. IP based surveillance systems
146. Forensic Tools (eg Windows Washer, Privacy Suite etc)
147. Anti-forensic tools (eg Evidence Eliminator)
148. The Insider- Fighting the Enemy within
149. Enabling the small business network
150. Comprehensive Vulnerability Management
151. Secure ID Applications
152. Protecting the desktop
153. Beware of online risks – enterprise users engage on riskier online behaviour than home users
154. EPS (End Point security)
155. Cyberslacking and corporate performance/losses
156. Data: Lost, stolen or strayed (off site backup storage for tapes etc)
157. Software Portfolio Management – The Proving Model
158. Maturity in process Model for Project Management
159. Ensuring the IT project Deliver Business Results
160. Technical and Organisational Transformations
161. Improving the Application of Risk Management
162. The next wave – Computer Systems that never Fail
163. The next wave – computers that think like humans
164. Scandal, Security and Strategy
165. Password Overload and Business Security

166. Storage Security
167. Illegal Downloads and business risk/costs/integrity...
168. Keyboards and their Impact on system productivity
169. Voice activated input system and their efficiency in business situations (such as Via Voice)
170. Cyber Café – A world of Business
171. The characteristics of a Modern IT manager
172. The changing role of the IT professional
173. The strategic Role of IT in business is Questionable
174. Flexible Working in IT – A way Forward
175. IT and Business Risk – Using IT Governance ITIL to minimise business risk
176. Compliance – an IT nightmare
177. Gaining the business edge with IT
178. IS Management in the SME/large corporation/government etc
179. Electronic bill presentment and payment
180. Critical Incident Management in IT
181. The Ethical Hack – A framework for business Value penetration attacks
182. Outsourcing Software Development Offshore
183. Designing Usable Electronic Text
184. Software Testing and Continuous Quality Improvement
185. Lightweight Enterprise Architectures - a way forward in cost control
186. The Role of Ethics in Systems Analysis
187. The effect of Ethical decision-making in the implementation of a Business Information System.
188. The role of Learned Societies (eg BCS) in ensuring professional Competence
189. IT and its role in Social Inclusion
190. Modern Software Development and its role is helping the disabled IT professionals
191. Screen reading Software Efficacy as a solution to enable the visually impaired to use business software
192. Speech recognition system increases widen participation rates/increase worker productivity/ etc
193. The role of Web Content Accessibility Guidelines in moving web sites into the modern era (see www.w3.org)
194. IT professionalism is essential for the full development of the industry
195. ILM (Information Life Cycle) – Controlling the Data Mountain
196. Business Costs associated with Sarbanes Oxley compliance
197. Business Advantages of Sarbanes Oxley compliance
198. Strategies for Sarbanes Oxley compliance Implementations
199. IT and Micro loans in Developing Countries (Gramēen Bank and such things)
200. Micro Payments a route to a cashless society
201. Blogging – A possible business Strategy
202. Blog Monitoring – A possible business Strategy?
203. Blogging – Is gagging bad for business
204. Domain name crime
205. Who owns the Internet – A big Company Takeover
206. Replacement of names and Passwords – What are the security and Usability Implications
207. New Security threats – rootkits
208. Multi-tasking OS a user boon or nightmare?
209. Web Based operating system – Is there a future?
210. Ultra Wide Broadband – and its impact on business
211. High Speed Broadband – it business impact
212. High Speed Brand and User services
213. Security – the users is his own worst enemy
214. Usability and its trade off with security
215. PDA Revival – Is there a Business Future?
216. Portable PCs and their business future (ie blackDog)
217. Security Software Interfaces and personal freedoms
218. Avatars – a way forward for websites?
219. Faces as passwords – a secure business alternative
220. Personal gadgets and Illegal Downloads – The curse of Organisations (iPod etc)

221. Management and IT Potential
222. Managing a business in and IT dominated world
223. IT reporting functions and Business Instinct
224. Managing IT system Integration
225. Managing business Continuity planning with highly integrated systems
226. Security Violation Reporting – How Management Deals with This huge Volume of Data
227. Business implications of the Web Bases OS
228. Microsoft Dynamics – A challenge to SAP and Oracle
229. Community Technology Previews – A Marketing Strategy or a genuine attempt to communicate
230. Adjacent Software – Securing Productivity for the User
231. Web 2 a new model of usage
232. Web based desktop tools and their use in business
233. Results oriented approach to the UI (instead of command-oriented – see 2006 MS office 12)
234. Small Business Accounting Software
235. Cyber-terrorism
236. Sourcing New Technology for enhancing business success
237. Optimising business functions by sourcing new technology

Appendix. A selection of Projects Ideas Approved in past Cohorts

Building a successful software industry in the Caribbean using Free, Libré and Open Source (FLOS) software Business and IT Alignment

Company policy on IT training affects user acceptance of IT system.

Desktop Security Threats and its Business Impact

Dispatching Engine And Mobile Communication Devices To Automate Service Delivery To Customer

Research Methods: Assessment No. 1a – Project Specification and Outline Literature Review**Introduction**

The full assessment plan for the Master's programme can be found in Workbook 1 of the workbook pack – you must ensure that you are familiar with it as the work here is only part of the overall plan. In this assessment you develop a project specification which is to be approved by a University panel.

Overall Research Methods Marking

You are reminded that this work is weighted and to assess whether you have passed the unit as a whole it will be combined with the statistics assessment in the ratio of $0.7 * \text{Assessment 1a} + 0.3 * \text{Assessment 2}$ where all assessment marks are expressed as a percentage. The overall pass mark is 40%.

Project Focus

The project you write later in the course must be based on the specification you produce here. The project must be coherent with the programme title, therefore, it must be

Research Based – means that you have to collect original data (called primary data) yourself. Primary data is not something you can get out of a book or just download from the Internet – it has to be totally original.

Strategic Business IT Orientation – the primary data you collect has to be used to generate a Strategic Business IT outcome of some kind.

IT learning – the project must represent significant learning potential in the IT/computing field for you.

Project Style – for this degree only the project style known as "Study" is allowed.

New Work - students are reminded that the project must be new work and you are NOT permitted to use any project material or data that may have been used before on another course or indeed for any another purpose. If it is discovered that previous project work or research material is being re-used it will result in immediate disciplinary action.

Restrictions

Project ideas in the following areas are unlikely to be accepted: [eBanking, eCommerce, mCommerce, eLearning, IT-in Education, Web Site Strategies, Outsourcing, wireless technology and systems, PDA and mobility, simple HCI, Music Distribution, VoIP, HelpDesks, CRM factors, or simple security.]

If you feel that you have a novel or new view on any of the above with a hint of originality within a Strategic Business IT framework then you should write to the Research Methods tutor outlining your new idea.

Work Schedule

Assessment 1a is made up of 3 parts. Some of the parts represent progress marks and others for the final work submitted for this part of the Research Methods Unit. To be successful, commitment, care and dedication to delivering your best possible work is needed. Therefore in summary

Part 1. Gaining title approval during the first few weeks of the course is worth up to 10 marks.

Part 2. Passing the online tests, one of which is set each week for 5 weeks is worth up to 5 marks.

Part 3. A short Literature Review and your MSc project specification is worth up to 85 marks.

Note.

Assessment 2 is for statistics and is NOT covered in this description and will be sent separately to you by the mathematics tutor.

Purpose

The purpose of this part of the work is to gain approval for a project idea from the University by writing short MSc project proposal. This is assessed work so you will only be allowed one attempt to gain the full range of marks. If for whatever reason your idea is rejected you may make another attempt but in such a case the maximum mark you can attain for this work is 4 out of the available 10.

Topic Area Selection

Select a title or an idea from Appendix C of this document or find one of your own and use it as the basis for writing a project proposal - there is an example in appendix A to this document.

Study References

The following Workbook and section references are to the Student Workbook Pack Release 2.8. If it is obvious by the quality of your submission that you have not studied this material with care the proposal will be rejected without comment.

Encouragement

You **MUST** expect to go backwards and forwards many times over all the headings until you have a concise, coherent and lucid proposal that is your very best work.

Submission

When your proposal is ready use WebCT email to send it to the Research Methods tutor in a text only (no formatting, no diagrams, no tables etc) message or as an attachment. You are advised to get title approval as early as possible but the tutor will not entertain ANY submission until the beginning of the third week of the unit and no two students will be allowed to use exactly the same topic.

Format and Word Limit

Write the proposal using the headings shown below but you must not exceed 450 words (including the headings). If the word limit is exceeded, any headings are missing, any headings are altered, the sequence of headings changed or any headings added the proposal will not be assessed and you will have to do it again. You must stick closely to the headings - for example, under the heading "Problem Definition" we expect to see ONLY a definition, not how you will solve it, topic discussion, a justification for the study, or indeed anything other than a problem definition. If you wander from the theme of each heading you will lose marks.

Project Proposal (Word Count = 450)

1. Title – Construct a title in not more than 100 characters. (workbook 6 section 6.12 will help you do this.)

2. Background – Give an overview of your topic area as background to understand how you identified the problem theme, but please note this section is NOT a description of what you are going to do, it is a description of the topic area.

3. Presenting Problem Definition – define a single significant IT or IT related problem that you are trying to solve. I suggest you be absolutely clear and say something like "The problem is X and my definition is ...". See Workbook 6 section 6.2 and 6.3.

4. Real-World Target – state what the real world benefit or effect there will be if the stated problem can be resolved or partially resolved by using your MSc project outcome. (See Workbook 6 section 6.10.1 and see Workbook 3 Section 3.2 and 3.4.2.)

5. Research Question – write a question you want to ask as a way of encapsulating the quest to resolve your problem theme with your stated target. (Use Workbook 6 sections 6.5, 6.7 and 6.8.)

6. Personal Theory – express concisely your personal theory about a possible resolution of this problem theme. See workbook 6 sections 6.3.

7. Intended Project Outcome – what is the form of your expected project outcome that arises naturally out of your personal theory and constitutes an answer to your Research Question? Use (Workbook 6 sections 6.2, 6.3, 6.5.4 and 6.7.) You should note that project outcome must be an object that can be placed in a document.

8. Strategic IT value – explain how obtaining the project outcome in the form that you have described above will have a strategic business IT benefit or IT related benefit that will be valued by business. (See sample in Workbook 4)

9. Design for Collecting Primary Data – this is the first part of your design to generate the stated project outcome. This part of the design sets out your process for creating a collection of primary data. The core of this process is called a Basic Activity for Generating Data. See (Workbook section 6.6, 6.7 and the study project specification sample and associated notes in workbook 3 sections 3.2.7 and 3.4.2.)

10. Design for Processing Primary Data — this is the second part of your design to generate the stated project outcome. Crucially here, you set out how you will process the collection of primary data in order to generate the stated project outcome. See the study project specification sample and associated notes which can be found in Workbook 3 sections 3.2.7 and 3.4.2.)

Here is a blank list of headings to help you formulate your project proposal.

1. Title –
2. Background –
3. Presenting Problem Definition -
4. Real-World Target –
5. Research Question –
6. Personal Theory –
7. Intended Project Outcome –
8. Strategic IT value –
9. Design for Collecting Primary Data –
10. Design for processing Primary Data –

Part 2. Online Tests – To be taken during the published date periods

Value = Up to 5 Marks

There are 5 on-line tests and these will be made available for a short time periods every week for the 5 weeks starting in week 2. For each test in which you score 60% or better you will receive one mark. To do these tests YOU must find out where they are on the WebCT site and make sure you take note of when the test are available. No exceptions will be made, if you miss any test for any reason you will NOT be able to take it at some other time.

Part 3. Short Literature Review and Project Specification – Due date 15.9.2006

Value = Up to 85 Marks

Purpose

Once you have an approved or permitted project proposal based on part 2 you are allowed to construct a short Literature Review and a full MSc Project Specification which will be marked by the Research Methods tutor and reviewed by a University panel for final approval. If your specification is not approved by the University you will have another opportunity to try again in the next available cohort either with the same title or with a new one.

Study References

The Workbook and section references found in the sample Literature Review and sample project specification are to the Student Workbook Pack Release 2.8 If it is obvious by the quality of your submission that you have not studied this material with care the proposal will be rejected without comment.

Encouragement

You **MUST** expect to go backwards and forwards many times over all this work until you have a concise, coherent and lucid short Literature Review and full MSc Project Specification.

Submission

When your proposal is ready use the correct WebCT Drop Box and send it to the University. Do NOT send it directly to the tutor unless you have difficulty and there is no time to contact the University. If you send it to the Tutor the University system will not be able to detect a submission and your work will be marked as late and capped at 40% or rejected entirely.

You may submit the work any time up to and including the due date. However, it is unwise to submit early as you may then find that subsequent learning makes you want to change what you have written.

Format and Word Limit

The Short Literature Review and MSc Project Specification must not exceed 3,000 words (including the headings) but excluding the reference list and project plan. In the specification if any major headings are missing, any headings are altered, the sequence of headings changed or any headings added the proposal will not be assessed and you will have to do it again. You must stick closely to the specification headings - for example, under the heading "Presenting Problem Definition" we expect to see ONLY a definition, not how you will solve it, topic discussion, a justification for the study, or indeed anything other than a problem definition. If you wander from the theme of each heading you will lose marks.

Checklist

The formatting details are set out in the checklist found in appendix B which must be included with your submission and is a declaration by you that the work is ready to submit.

Part 3: Section 1 - Literature Review worth up to 25 marks

800 - 1,000 w = 2 1/5 pages.

References - see Workbook 4, Workbook 5 especially Section 5.1 and Workbook 9 Section 9.6.5)

Process - In order to carry out the project work you must have a fully prepared mind and that preparation is carried out using a thorough Literature Review. However, in this section we only expect a short review so that the University can assesses your commitment, scholarly assets and preparedness for moving to the project phase. It is hard to be precise here but a short review of between about 800 and 1,000 words is normally adequate.

Part 3: Section 2 - MSc Project Specification up to 60 marks

1,500 - 2,000 w = 2 1/5 pages.

References - see Workbook 3 section 3.1, 3.2 and 3.4.2

Process - To write up this work use the study project style headings and format located at the above references. You are advised that the tutor is not permitted to read your specification before submission as it must be seen to be entirely your own work since it is a formal assessment. However, the tutor will be happy to accept specific questions or discuss aspects of your work related to the various research elements and principles. It is hard to be precise here but good specifications are typically about 1,500 to 2,000 words.

Warning - to be able to move to the project supervision stage you MUST achieve a mark of at least 35 in the project specification.

It is therefore possible, that you could pass the Research Methods unit but judged, because of a poor specification, as not ready to be allocated a project supervisor and begin the project itself. If this happens to you will be allowed to just submit the project specification again in the next available cohort but your overall Research Methods result will not be affected.

Appendix A. Sample Approval Submission

This is a sample submission for guidance and you should NOT attempt to try to fit your idea onto it as if it were some sort of template in an attempt to reduce the work you have to do - if the tutor believes you are doing that your work will be rejected

The difficult elements are typically to be absolutely consistent and secondly to find an appropriate BAGeD. By consistency is meant that the whole submission links together and we don't find such things as the project outcome mentioned as X in one place and Y in another or the problem theme starts off as A in under one heading but migrates to B under another. If such inconsistencies are discovered, you will lose marks or be rejected outright.

Project Proposal (Word Count = 412)

1. Title – Phishing – Preventative Measures

2. Background – email is a technology that almost everyone uses in the home, at work or on the move. Traditionally, email is a simple one-to-one or one to many message passing technology but it is now offered with enhancements that include voice, video, chat, file passing and file sharing where suppliers are attempting to present a complete communication environment. Difficulties are often attached to such technologies one of these is identity theft and one way of doing this is known as Phishing.

3. Presenting Problem Definition - Phishing is identity theft using email where a personal message seeks confidential or private information from its recipient whilst posing as a legitimate request. The intention therefore is to fool the recipient of the message into releasing information which can subsequently be used for fraudulent purposes.

4. Real-World Target – Increase the awareness of computer users about the nefarious activity of Phishing and hence help prevent identity theft occurring and therefore reducing cases of fraud.

5. Research Question – How can Phishing be reduced or eliminated by generating awareness in computer users in order to reduce the risk of inadvertently releasing confidential or private information and hence incurring loss.

6. Personal Theory – Phishing is an attempt at fraud and relies on unsuspecting individuals giving away confidential or private information. I believe this can be combated by developing a document outlining available strategies for users who may be unsure what actions to take.

7. Intended Project Outcome – my expected form of outcome will be a set of guidance notes on effective strategies to use (including examples) in the event of a Phishing incident occurring.

8. Strategic IT value – the online guidance notes may go some way to preventing or reducing successful Phishing and this will imply that our company employees are more secure and that should lead to a reduction in risk and possibly higher productivity.

9. Design for Collecting Primary Data – the BAGD will be to look for phishing instances. My process will be to draw up a list of known phishing examples and use that to guide me in searching email logs for identifiable incidents followed up by interviewing selected personnel

10. Design for processing Primary Data – once I have the primary data in the form of a collection of phishing incidents I will classify them into general types and based on each type I will devise an illustration and a strategy to combat it contained in a set of guidance notes.

Appendix B – Submission Check List for Assessment 1a Part 3

This form must be included as an appendix to the submission of part 3 of this assessment and it is intended to show you that you have correctly formatted work and included all that is needed.

If you are unable to tick every box then your work is not ready for submission. If boxes are ticked and it is subsequently found that the relevant element is not present it will be taken as a deliberate attempt by you to falsify the record and the work will be returned to you unmarked and disciplinary action initiated with the work automatically regarded as a fail.

Word Count		The maximum permitted word count is 3,000 excluding project plan and reference list.
	I have written down the word count and it does not exceed the permitted value	
	I have used the correct margins of 2cm top, bottom, right and left	
	The work presented is an A4, MS .doc format document in portrait orientation (project plan may be presented in landscape)	
	I have used Ariel narrow font at 12pt size except in the project plan, reading list and page footer where I have used 10pt.	
	I have used a line spacing of 6 lines/inch	
	The first page uses the assessment heading line shown on the specification sample in workbook 3 section 3.4.2	
	I have used the correct format for a specification as found in workbook 3 section 3.4.2	
	Pages have centred footers in the form - Page 1 of 5 - J.J. Letto HEMIS No. 567543 Submission Date: 2004/05	
	I have not used page headers	
	The submission file is named using only my HEMIS Number (if anything else is added your file will be automatically deleted)	
	I have sent my personal profile to the Research Methods tutor	
	All main text is right and left justified	
	Headings are NOT followed by a blank line	
	Headings are in the same font as the main text but are shown in bold	
	I have used a blank line to separate paragraphs	
	I have not numbered any paragraphs or sections	
	I have looked up and studied ALL the references mentioned in this assessment	
	I have cited other people's work properly using the Harvard APA format	
	I have included all citation sources in my list of references	
	I understand that indented sentences can be used where appropriate but bullets are not to be used	
	I have included a references list of at least 10 literature sources	
	My reference list contains no more than thee books covering Research Methods and Statistics	
	I have only used the citation form (Briggs 1999) for passing references to texts	
	I have included at least 3 sources covering the core topic area of this research	
	In the reference list no more that 20% are internet sources	
	The specification includes a plan to get original data (primary data) and I do not have that data already	
	I have ensured that the primary data collected can be used to generate a Strategic Business IT outcome of some kind.	
	The project has a significant learning potential in the IT/computing field	
	I understand for this degree only the project style known as "Study" is allowed.	
	My Literature Review is not be made up of just quotes and paraphrase but is an evaluative dialogue	
	Plagiarism Declaration - I confirm that the enclosed written work is entirely my own except where explicitly stated otherwise. I further declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions. I further understand that wherever 6 or more consecutive words are extracted from a source they must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.	

Appendix C. Project Topic Ideas

Some ideas for final Projects and for use in this assessment – you don't have to select one of these they are just to give you a flavour of what you might look at. The list below was written as general ideas but they could always be applied to a particular situation as well.

No two students will be allowed to use exactly the same idea so it is important for you to get started before all the good ideas are selected and allocated.

1. Desktop Lifecycle Management – A new MS Provision
2. The effect on Profitability of implementing an IT supported Asset management system
3. Insuring IT based data assets and certification needs (BS 7799 ISMS)
4. The effect of IT systems on company Policy
5. The effect of company Policy on IT procurement
6. How company policy drives IT system selection
7. High Quality IT systems increases worker commitment
8. Highly Integrated systems such as SAP increases worker commitment
9. Highly Integrated systems such as SAP increases worker stress
10. Reliance on private computer systems increases the costs of worker stress
11. How IT can help with Life Cycle logistics in asset Management systems
12. Life Cycle logistics in IT systems
13. How important is user acceptance in the utility associated with IT systems
14. Company policy on IT training affects user acceptance of IT system
15. The impact on worker productivity/morale of removing all personal systems
16. IT Project Management Practice could be improved by the Use of Emotional Intelligence
17. Configuration Management Software in large scale IT installations
18. The impact of Internet enabled systems on resource usage
19. Assess and justify the rational use of the ILS techniques on future IT projects
20. IT outcomes that may prove useful in justification of application of ILS
21. Recommend a corporate strategy with ILS as a core profit center
22. Cost-benefit analysis justifying resource application to achieve IT supportability objectives
23. How ILS is applied to IT acquisition programs and their relation to outside influences
24. Appraise and predict the consequences of inappropriate application of IT Systems
25. Techniques for costing IT support requirements
26. Possible cost-based processes as critical management tools with regard to IT
27. Analyse, plan, evaluate or report on an IT Project
28. Define the role of ILS in a commercial sector IT procurement programmes
29. Explain the implications of ILS usage in IT installations
30. Report on commercial applications of ILS techniques or philosophies
31. IT and Logistics Management
32. IT ethics and the economy/business
33. eAuction - The Future of Procurement?
34. Teleworking and IT professionals
35. Enterprise permeability and the supply chain
36. Impact of IT on international supply chain management
37. The impact of IT on global manufacturers
38. IT and Technology in Sport
39. Forensic IT
40. Telemedicine
41. Knowledge Management and its place IT planning/procurement/success etc
42. Web Services – The future for distributed systems (.NET and J2EE etc)
43. Computing Industry standards and their impact on business
44. Software Maintenance – A company wide strategy for business support
45. Software risk management and its implication for IT strategies
46. IS needs must be matched to value in that IS systems can only be successful if there is a causal link to business success.
47. The impact of IT on financial service provision has been significant.
48. Micro-payment systems – the route to a cashless Society
49. Modern HRM systems have had a major impact on recruitment and retention of staff in large organizations.
50. Attempting to integrate all systems in a company is unwise

51. Modern developments in integrated storage management
52. The Effect of dual or triple core processors on worker productivity
53. Data life cycle management
54. The role of IT training in ensuring personal productivity
55. How new technologies related to location commerce might affect business policies
56. Software Agent technology and its future role in mobile computing
57. Software agent technology and its role in improving search engine performance by profiling usage.
58. Software Agent Technology and its use in improving web applications
59. eMail - a Business Nightmare
60. Mobile email – Taking a business Lead
61. Dealing with email enquires in large corporations
62. The role of eMail in a modern business Organization
63. eMail and ISPs
64. eMail and the personal user
65. eMail storage Systems and their impact on business
66. eMail currency and its impact on personal productivity
67. The impact of Spam on personal productivity
68. Then effects on business of organizations such as SPEWS in limiting SPAM
69. SPF (Sender Policy Framework) An Answer to SPAM
70. Phishing – a personal tragedy and a corporate nightmare?
71. Skype and its use as a viable business communication suite
72. Content Management systems and their place in a Modern Organization
73. IT and Business Risk
74. IT hardware – A never ending Cost Centre
75. Storage Area Networks and their Impact on Business Policy
76. Modern Societies Dependence on Electronic Storage
77. The Paperless Society – an impossible dream?
78. Document Management Strategies
79. Outsourcing Document Management
80. Making better IT Investment Decisions
81. Strategic Issues in Document and Information Management
82. Developing a corporate Strategy for Document and Information Management
83. Document Management and support for Critical Business processes
84. Electronic Documents and Record Management
85. The requirements gathering process is a major cause of project Management Failures
86. The role of IT as a strategic Business Resource
87. IT/Computing standardization of systems and the impact on business success
88. IT/Computing standardization of systems and the impact on business policy
89. IT Infrastructure and Business Continuity Planning
90. Business Continuity Planning – A Replacement for IT Disaster Recover
91. The Role of IT Certification in Systems Operational Performance
92. The Role of IT Certification in terms of Strategic IT Development
93. The Role of IT Certification in Implementation Strategies
94. IT Service Management and Business Success
95. IT Security Management and its Impact on Business success
96. IT Service Levels Agreement and Business Strategies
97. IT training issues and the disabled workforce
98. IT Collaboration Tools and Business Success (email, Intranets, shared files systems, desktops, user profiles etc)
99. Teleworkers and their Impact on IT security, business success, outsourcing etc.
100. IT Application and Organisational Change
101. The role of user training in Requirements gathering
102. The role of prototyping and user involvement in requirement gathering and proving
103. The role of emotional indigence in IT user support
104. Implementation and training for BizTalk or Sharepoint Portal Server or Content Management Server rtc
105. The role of BizTalk or Sharepoint Portal Server or Content Management Server in business success
106. SAN and Continuous Data Protection
107. Entry level SAN and the SMB/SME

(Project management)

108. Legacy Data and BI Tools sets
109. Leveraging Data and BI tools sets
110. RFID in a retailing Context
111. RFID in Baggage Handling
112. SPAM – An analysis of common content
113. The Extended Enterprise (networks of suppliers, eProcurement etc)
114. Search Engines and business Efficiency
115. The IP enabled Economy
116. Optimisation of IT services (eg HP OpenView)
117. Hackers – Looking for fortune not fame
118. The adaptive Enterprise (that is growing IT as it is needed)
119. Migration Practices for Legacy Systems and Business Planning
120. IT Strategies and External Business Factors
121. eGov in the Middle East
122. eBooks and Readers – their use by business
123. Performance and Power – GRID Computing (can the power available lead to increased business performance)
124. Anti-spyware – a business and personal necessity
125. Cyber spying
126. IP based surveillance systems
127. Forensic Tools (eg Windows Washer, Privacy Suite etc)
128. Anti-forensic tools (eg Evidence Eliminator)
129. The Insider- Fighting the Enemy within
130. Comprehensive IT Vulnerability Management
131. Secure ID Applications
132. Protecting the desktop
133. Beware of online risks – enterprise users engage on riskier online behaviour than home users
134. EPS (End Point security)
135. Cyberslacking and corporate performance/losses
136. Data: Lost, stolen or strayed (off site backup storage for tapes etc)
137. Software Portfolio Management – The Proving Model
138. Service-Oriented Architectures (SOA) – A new breed of Applications
139. Improving Best practice in IT support units
140. Taking a cross-organisational approach to IT
141. IT needs to be at the heart of all business plans
142. Managers Manage but Technology Enables
143. Organisational benefits of security surveillance
144. The Evolution of the Intelligent network and its business impact
145. Ensuring the IT projects Deliver Business Results
146. Improving the Application of IT related Risk Management
147. The next wave – Computer Systems that never Fail
148. The next wave – computers that think like humans
149. The computer gadget market and its impact of Business IT
150. Password Overload and Business Security
151. Storage Security
152. Illegal Downloads and business risk/costs/integrity...
153. Keyboards and their Impact on system productivity
154. Security in Kiosk installations
155. Usage patterns in Kiosk installations
156. Voice activated input system and their efficiency in business situations (such as Via Voice)
157. Cyber Café – A world of Business
158. The characteristics of a Modern IT manager
159. The changing role of the IT professional
160. The strategic Role of IT in business is Questionable
161. Flexible Working in IT – A way Forward
162. Compliance – an IT nightmare
163. Gaining the business edge with IT
164. IS Management in the SME/large corporation/government etc

165. Electronic bill presentment and payment
166. Critical Incident Management in IT
167. The Ethical Hack – A framework for business Value penetration attacks
168. Lightweight Enterprise Architectures - a way forward in cost control
169. The Role of Ethics in Systems Analysis
170. The effect of Ethical decision-making in the implementation of a Business Information System.
171. The role of Learned Societies (eg BCS) in ensuring professional Competence
172. IT and its role in Social Inclusion
173. Modern Software Development and its role is helping the disabled IT professionals
174. Screen reading Software Efficacy as a solution to enable the visually impaired to use business software
175. Speech recognition system increases wider participation rates/increase worker productivity/ etc
176. The role of Web Content Accessibility Guidelines in moving web sites into the modern era
177. IT professionalism is essential for the full development of the industry
178. ILM (Information Life Cycle) – Controlling the Data Mountain
179. Business Costs associated with Sarbanes Oxley compliance
180. Business Advantages of Sarbanes Oxley compliance
181. Strategies for Sarbanes Oxley compliance Implementations
182. IT and Micro loans in Developing Countries (Grameen Bank and such things)
183. Micro Payments a route to a cashless society
184. Blogging – A possible business Strategy
185. Blog Monitoring – A possible business Strategy?
186. Blogging – Is gagging bad for business
187. Domain name crime
188. Who owns the Internet – A big Company Takeover
189. Replacement of names and Passwords – What are the security and Usability Implications
190. Awareness Training on Internet Perils for Company Staff
191. The Organisational Burden of Software Licensing Schemes
192. Vendor Service and Software Licensing
193. Mobile Technology Offers Staff a more satisfying work-life balance
194. Business Skills needs of IT Security Officers in Organisations
195. Web Based operating system – Is there a future?
196. Ultra Wide Broadband – and its impact on business
197. High Speed Broadband – it business impact
198. High Speed Broadband and User services
199. Security – the users is his own worst enemy
200. Usability and its trade off with security
201. PDA Revival – Is there a Business Future?
202. Portable PCs and their business future (ie blackDog)
203. Security Software Interfaces and personal freedoms
204. Personal gadgets and Illegal Downloads – The curse of Organisations (iPod etc)
205. Management and IT Potential
206. Managing a business in and IT dominated world
207. IT reporting functions and Business Instinct
208. Managing IT system Integration
209. Managing business Continuity planning with highly integrated systems
210. Security Violation Reporting – How Management Deals with This huge Volume of Data
211. Business implications of the Web Bases OS
212. Microsoft Dynamics – A challenge to SAP and Oracle
213. Community Technology Previews – A Marketing Strategy or a genuine attempt to communicate
214. Adjacent Software – Securing Productivity for the User
215. Web 2 a new model of usage
216. Web based desktop tools and their use in business
217. Results oriented approach to the UI (instead of command-oriented – see 2006 MS office 12)
218. Small Business Accounting Software
219. Cyber-terrorism
220. Sourcing New Technology for enhancing business success
221. Optimising business functions by sourcing new Information technology

222. Digital Paper – A new Business Tool

223. Microsoft Office Business Scorecard Manager – A modern Management tool

Appendix. A selection of Projects Ideas Approved in past Cohorts

Building a successful software industry in the Caribbean using Free, Libré and Open Source (FLOS) software
Business and IT Alignment

Company policy on IT training affects user acceptance of IT system.

Desktop Security Threats and its Business Impact

Dispatching Engine And Mobile Communication Devices To Automate Service Delivery To Customer

eAuction- The Future of Procurement?

email in a modern business organization

Exercise 002a.01.q – Writing Research Questions

Try to remember that a good Research Question has several features but the most important of which are that it link problem and target and imply an expected form of answer. So ask:

- What problem is stated?
- What target is mentioned?
- Is there a data spotlight (where does the data come from)
- What sort of answer would I give? (a general description, a process description, an explanation, a definition, an exploration, a model etc)

Exercise

Look at the following Research Questions extracted from student work- which all have faults of one sort or another and say what these faults are. Don't shirk this exercise; take a few minutes to sketch out your view on each one, because you might otherwise fall into exactly the same trap.

1. Research Question - How redundant business processes be integrated to boost business performance?

Problem:
Target:
Data Spotlight:
Answer Form:

2. Research Question - What can be done to ensure successful implementation of OSP? ?

Problem:
Target:
Data Spotlight:
Answer Form:

3. Research Question - How can the awareness of the use of IT be used in order to ensure a better future for SMEs?

Problem: IT IMPLEMENTATION
Target: BUSINESS PERFORMANCE FOR SME
Data Spotlight: BUSINESS
Answer Form:

4. Research Question – The project will focus on the conceptual clarity on eTS, followed by basic eTS structure, sample programmes applied on products, and bring out the limitations on eTS. A literature and bibliography will be enclosed for further study.

Problem: IT IMPLEMENTATION
Target: BUSINESS PERFORMECE FOR SME
Data Spotlight: BUSINESS
Answer Form: BUSINESS

5. Research Question - What better strategy will be suitable to protect the organization's businesses from being disrupted by cyber terrorist attacks?

Problem: HACKING
Target: SECURITY
Data Spotlight: USERS
Answer Form: SECURITY MODEL BASED IN HARDWARE

6. Research Question – How can IP telephony system be used to enhance IT operations and procedures in order to improve network operations and potential cost savings?

Problem:
Target:
Data Spotlight:
Answer Form:

Exercise 001c.01.q – Analysing Problem Definitions

Here is an extended example of student work where we have a very poor and much laboured problem definition and to me it exposes the student's obsession with a particular solution. Try to analyse what is written and write a short report to the student explaining what you think is wrong here.

Student Example Problem Definition

The problem theme for computer maintenance staffs is focusing on incompetence at working environment whereby staffs find that it is complicated to handle new problems regarding hardware and software at real-time. Some new problems appeared in all of sudden in the computer system, which this makes most staffs are not capable enough and expertise to solve the new problems immediately that to meet to the requirement of clients at the quality time frame given. Moreover, staffs used to take much time to solve the problems and in terms of that also they kept postponed to the next days and times in very often which these makes most clients get frustrated, lost confident and unsatisfied with their service. In addition, management also faced with low productivity which effect to the organization profit.

Comment

Add your feedback to the student here.

Student Example Theorisation (speculation)

The problem solution from this research is to supply educational technology training for computer maintenance staffs for updating their knowledge about new technology by exposing them in the real-time in handling new problems so that they will be well-versed with the new problems arrived and technology evolved in the current market. When employee updating their knowledge about new technology via educational technology training, they will absorb new skills and technology and become a quality employee which will improve their troubleshooting performance. Moreover they will also expertise to solve any new problems in hardware or software at any kind of scenario. In addition, they will also be producing a high quality of work at a high quality of time, which also will increase the productivity.

Comment

Add your feedback to the student here.

A Possible Formulation

Write some notes here that would help the student arrive at a suitable formulation for a research project using the 4 key headings: **Problem, Target, Theorisation/Speculation and Outcome Form** -

Research Methods: Assessment – Project Specification and Outline Literature Review**Introduction**

In this assessment you develop a short literature review and project specification which is to be approved by a University panel. The overall pass mark is 40%.

Project Focus

The study project you write later in the course must be based on the specification you produce here. The project must be coherent with the programme title, therefore, it must be

Problem-Solving Based – meaning that you have to investigate a real problem, which may be based on the work that you do for your organization, and collect original data (called primary data) yourself. In some cases, data sets may be given to you. You may also select a topic from the list provided in Appendix E.

Strategic Business IT Orientation – the primary data has to be used to generate a Strategic Business IT project outcome of some kind.

IT learning – the project must represent significant learning potential in the IT/computing field for you.

New Work - projects must be new work and you are NOT permitted to use any project material or data that may have been used before by you on another course or indeed for any other purpose. If it is discovered that previous project work or research material is being re-used it will result in immediate disciplinary action.

Schedule of work to be done**Pre-Work 1. Induction Checklist****Due Immediately but cut off date 13.4.2007**

You must complete the induction checklist shown in Appendix A and send it to the Research Methods tutor, Mr Fred Garlick, in a WebCT email. If the checklist is not received by the cut off date your registration may be revoked and fees forfeited.

Pre-Work 2. Personal Profile**Due Immediately but cut off date 13.4.2007**

You must complete a personal profile as shown in Appendix B and send it to the Research Methods tutor, Mr Fred Garlick, in a WebCT email. If the profile is not received by the cut off date your work will not be assessed and you will be recorded as a fail.

Pre-Work 3. Online Tests**Each test must be completed within the date period stated in Webct**

It is recommended that you complete these self tests in the first 5 weeks as they are designed to take you through the notes in a systematic manner. The score you should aim for is to get at least 65%. The marks will not count towards your Research Methods mark but doing the tests will help you in studies and will assure the University assessment panel that you are committed to the course.

Pre-Work 4. Project Approval**Due any time after week 2 but cut off date 27.4.2007**

Purpose - It is necessary to get your project idea approved during the first few weeks of the course, based on a simple written project outline. Failure to gain approval will mean that you cannot attempt the assessment itself.

Topic Area Selection - Appendix E contains a list of topic ideas which show you the range of possibilities for the project. The key point is that you must be able to collect or be given by the University primary data and it must be possible to regard the topic as Strategic Business IT.

Study References - The study references given throughout this assessment are to the Student Workbook Pack CN.002 Release 3.3 which you must download from the WebCT site using the SBIT resources and Information section.

Submission - When your proposal is ready use WebCT email to send it to the Research Methods tutor in a text only (no formatting, no diagrams, no tables etc) message – it must **NOT** be sent as an attachment. You are advised to seek approval as soon as possible but it would be very unwise to try to do it until after the first two formal subject area chat sessions.

Format and Word Limit - Write the proposal using the headings shown below but you must not exceed 400 words (including the headings and declaration). All work is submitted with a declaration and this must be offered honestly. **A fully worked sample can be found in Appendix C.**

Requirements – the expectation is that you will prepare this work thoroughly and only submit your very best work. The tutor is there to help you prepare but will NOT look at multiple drafts until you get it right. You are however, encouraged to discuss with him any difficulties you have at any time.

Project Proposal (Word Count =, Student Number =)

Declaration – <student name> confirm that I have carefully studied all the Workbook references in constructing this proposal and that what is described here is a new work and is not copied from any source.

1. Title – Construct a title in not more than 100 characters. (Study workbook 6 section 6.14).

2. Problem – define a single significant problem for which you are going to find a solution route. Problems are such things as: inaccuracy in data entry, lack of motivation, slow and inaccurate responses to audit requests, inability to maintain competitiveness in a rapidly changing business world, learning difficulties in online courses, vestigial manual processes after the implementation of CRM, data losses in supposedly secure systems and so on. (Study Workbook 6 section 6.2 and 6.11)

3. Real-World Target - these are the effects that will be observable and measurable in the real world if the problem can be solved by using your project outcome in some way. It is permissible to list more than one effect but it is best to look for the principal one. Targets are such things as: efficiency gains, provide or enable better communication, increased accuracy, increased awareness and so on. (Study Workbook 6 section 6.3 and 6.8.5)

4. Project Outcome – this is the object you will generate as the final product of your MSc project. Possible outcomes are characterised by nouns so might be: reports, models, frameworks, policies, strategies, position papers, reviews, procedure descriptions, best practice descriptions, lexicons, dictionaries, concordances, protocols, diagrams, charts, plans, etc. You must define the outcome and show that you really understand what it is as a structure and what it contains as your outcome. For example, if you say that your outcome is a policy then we must be able to see from what you write that you indeed do know what a policy is supposed to be and what it will contain. (Study Workbook 6 section 6.4 and 6.8.5)

5. Actor - It is normal when you define your outcome to say who the actor or actors are (meaning persons) who will use your defined outcome and then show that its use by them leads to the target effects. Actors might be anyone who can use the outcome: departmental managers, computer users, IT migration teams, sales staff, software developers and so on. (Study Workbook 6 section 6.5 and 6.8.5)

6. Research Question – this is a sentence expressed as a clear question that connects the various elements and expresses the direction of your research and summarises your whole project. You should note that there are 6 elements to a good Research Question and they must all be present in whatever you write. (Study Workbook 6 section 6.8)

Here is a set of headings for you to use but make sure you study with care the format as well as the sample that can be found in Appendix C and **all** associated references,

Project Proposal (Word Count =, Student Number =)

Declaration – I <student name> confirm that I have carefully studied all the Workbook references in constructing this proposal and that what is described here is a new work and is not copied from any source.

1. Title –

2. Problem –

3. Real-World Target -

4. Project Outcome –

5. Actor –

6. Research Question –

Purpose – Once you have an approved or permitted project proposal you are allowed to construct a short Literature Review and a full MSc Project Specification which will be marked by the Research Methods tutor and reviewed by a University panel. If your specification does not get at least a 40% pass marks you will have another opportunity to try again in the next available cohort either with the same project title or with a new one.

Encouragement - You **MUST** expect to go backwards and forwards many times over all this work until you have a concise, coherent and lucid short Literature Review and full MSc Project Specification.

Submission - When your assessment attempt is ready, use the correct WebCT Drop Box and send it to the University. Do NOT send it directly to the tutor unless you have difficulty and there is no time to contact the University. If you send it to the Tutor the University system will not be able to detect a submission and your work will be marked as late and capped at 40% or rejected entirely. You may submit the work any time up to and including the due date. However, it is unwise to submit early as you may then find that subsequent learning makes you want to change what you have written.

Format and Word Limit - The Short Literature Review and MSc Project Specification must not exceed 2,500 words (including the headings) but excluding the reference list and project plan covering about 6 pages. In the specification if any major headings are missing, any headings are altered, the sequence of headings changed or any headings added or you have not used the format shown in the Workbook Pack CN.002 Release 3.3 section 3.5.2 the proposal will not be assessed and you will be recorded as a fail.

Weighting – each element is marked out of 100 but to calculate the overall assessment score the short literature review will be weighted at 0.25 and the Specification 0.75

Checklist - The formatting details are set out in the checklist found in appendix D which must be included with your submission and is a declaration by you that the work is ready to submit. A penalty will be applied of 2 marks for every departure found in your work from the requirements found in the checklist.

Requirements – the expectation is that you will prepare this work thoroughly and only submit your very best work. The tutor is there to help you prepare but will NOT look at multiple drafts until you get it right. You are however, encouraged to discuss with him any difficulties you have at any time.

Literature Review worth up to 100 marks

References - see Workbook 4, Workbook 5 especially Section 5.1, 5.6 and 5.7 and Workbook 9 Section 9.7.5.

Process - In order to carry out the project work you must have a fully prepared mind and that preparation is carried out using a thorough Literature Review. However, in this section we only expect a short review so that the University can assesses your commitment, scholarly assets and preparedness for moving to the project phase. It is hard to be precise here but a short review of between about 800 and 1,200 words is normally adequate.

MSc Project Specification up to 100 marks

References - see Workbook 3 section 3.1, 3.3 and 3.5.2

Process – To write up this work use the study project style headings and format located at the above references. You are advised that the tutor is not permitted to read your specification before submission as it must be seen to be entirely your own work since it is a formal assessment but see requirements above. It is hard to be precise here but good specifications are typically about 1,500 to 2,000 words.

You should also complete the Ethical Examination Questionnaire and submit it at the same time as the Short Literature Review and Project Specification but sent directly to the Research Methods tutor. This will not be marked but if it is absent, your specification is incomplete and will not be marked, resulting in a fail for this unit.

Appendix A – Induction Checklist

Welcome 003a.01 - Induction check list		
Full Name:		HEMIS Number:
<p>1. All students, including repeating ones, must complete this checklist by the cut off date and send it to the Research Methods tutor (Mr Garlick). The checklist is to help you make sure you are prepared for the course and to do that the list requires a tick in EVERY box as confirmation that you have done everything that is needed to begin the course. Send it as an email attachment named with just your Student number (do NOT use your NCC number) – if anything else is added the system will automatically reject it and you will have to do it again.</p> <p>2. At the same time as you send in your checklist it is useful to also send your profile as defined in Appendix B.</p>		
1.		I have located the email section of WebCT
2.		I have read CN.002 3.3 Section 2.1 and understand what is required of a personal email account for use on this course
3.		I have created a single personal internet based email address that will be used for the duration of the course
4.		I have set mail forwarding in ALL my WebCT accounts to my personal internet based email account
5.		I have downloaded a copy of HB.001 3.0a Student Handbook
6.		I have located the course information resources section in WebCT
7.		I have downloaded a copy of the Student Web Site Guide
8.		I have downloaded a copy of CN.001 3.2a MSc Research Methods Notes
9.		I have downloaded a copy of CN.002 3.3 Student Workbook Pack
10.		I have downloaded a copy of CN.003 3.2a MSc Statistics Notes
11.		I have downloaded a copy of 2007 03 Assessment - Short Literature Review and Project Specification
12.		I have downloaded a copy of the Research Methods map (electronic form only)
13.		I have downloaded a copy of the Research Methods Project Map (electronic form only)
14.		I have downloaded a copy of the Chat and course schedule and personally diarised all relevant dates and times
15.		I have downloaded a copy of the Normal Probability Tables
16.		I have located a copy of University Academic Regulations
17.		I have located a copy of the ECF Form and Guidelines
18.		I have noted that the Assessment is in several parts and personally diarised the relevant cut off and due dates
19.		I have noted that the Assessment Pre-Work 4 deals with approval based on a Project Proposal.
20.		I note that the tutor will NOT read multiple drafts of assessed work though I may ask questions at any time.
21.		I have located in WebCT the 5 online tests and noted the dates when they will be active for me to take
22.		I have noted that the Assessment contains a short Literature Review, worth up to 100 marks
23.		I have noted that the Assessment contains Project Specification worth up to 100 marks
24.		I have noted that I must complete an Ethical Examination Questionnaire and submit it with the my project Specification
25.		I have located the Drop Boxes for posting the Assessment when it is due
26.		I have made a note of where the chat logs archives are located in WebCT
27.		I have located the chat rooms and entered one of them to ensure that I can gain access when required
28.		I understand that extra chat (for questions, comments and grumbles) will be available almost every week at 1400 Sunday
29.		I have downloaded and installed a copy of StarTreeStudio3 and examined the two maps mentioned above.
30.		I have read section 1 of CN.002 Release 3.3 and noted the overall assessment pattern of the MSc course
31.		I have read section 1 of CN.002 Release 3.3 and noted the assessment pattern for the Research Methods unit
32.		I have read section 2 of CN.002 Release 3.3 and made a study plan for myself (you may be asked for a copy)
33.		I have located the plagiarism declaration in CN.002 Release 3.3 and know I will have to use it in all submitted work
34.		I have located the Discussion Board and posted a greeting to my fellow students in the thread called Café
35.		I understand that I must get and submit a letter of support from the organisation where I intended to collect primary data
36.		I understand that if my project outcome is not based on primary data it will not be accepted
37.		I understand that the project work must be a new and not a modification or extension of something I have done already
38.		I understand that this checklist does not cover the statistics part of this course and I must discover that information
39.		I understand that all work must be completed by the cut of or dues date and no extension will be given.

Appendix B. Personal Profile

This profile must be sent to the Research Methods lecturer (Mr Garlick) via WebCT in text only message of no more than 350 words (including headings). The University will use this information to guide you in project title submission and selection. The profile will be available to the University panel that approves your specification.

Profile (Word Count = ??)

1. **Student No:** This is issued by the University
2. **Full Name:**
3. **Job Title:** Your current job title (or state unemployed),
4. **Company Name:** where you currently work (or write none)
5. **Company Profile:** briefly state the major business of you company (or write none)
6. **Country:** where you currently reside
7. **Job Description:** describe your core work (if unemployed say what work you would like to do)
8. **Years IT Experience:** state the number of years that you have had significant professional IT/Computing experiences
9. **Area of Expertise:** list no more than 3 areas in which you regard yourself as expert.
10. **Formal Academic Qualifications:** list in abbreviated form all your higher level certificated qualifications.
11. **Other Qualifications:** list in abbreviated form other qualification such as MCE
12. **Acceptance Basis:** explain briefly on what basis your PgD College accepted you onto the MSc part of the programme
13. **College Name:** this must be the name of the College where you gained your NCC Strategic Business IT PgD. Please make sure the name is correct.
14. **Academic Project Experience:** briefly describe the last academic project you completed.
15. **Email Address:** the one you expect to use for the duration of the course which must be the same as the forwarding address you set for your various email accounts in WebCT.

Example Profile (Word Count = 178)

1. **Student No:** 903210
2. **Full Name:** James Sheene-Southwood
3. **Job Title:** IT Project Manager
4. **Company Name:** BlueBird Systems Ltd
5. **Company Profile:** bespoke software in ticketing systems
6. **Country:** England
7. **Job Description:** Managing Business Systems Applications Developments including Requirements Gathering, Business Analysis and System Design using Prince2 methodology mainly in the Inventory Management area.
8. **Years IT Experience:** 6 years
9. **Area of Expertise:** Project Management practices but I also have some experience in Web based development and technologies within an IBM AS/400 environment
10. **Formal Academic Qualifications:** BSc (Hon) Computing, PgD SBIT
11. **Other Qualifications:** none
12. **College Name:** Purpletrain.com UK
13. **Acceptance Basis:** my first degree and 5 years computing experience
14. **Academic Project Experience:** Last academic project was a Web based ticketing system for a laundry service. Professionally my most recent work covered Technical Design of a web based invoice processing system for a UK holiday company
15. **Email Address:** james.sheene@googlemail.com

Please remember I don't want a copy of your job specification I just need to feel I concisely and precisely know who you are, what you do and where skills you have.

Appendix C. Sample Project Proposal

This is a sample submission for guidance in preparing your own project proposal. Please remember that you must use the set headings, you must study all the references and it must be your very best work. If you submit work that is very poor or show obvious signs that you have not prepared well or ignored the references the work will be returned without comment and a note made in your student record.

If you are unsure about any aspect or about the topic you will use then discuss it with the tutor before making a submission

Project Proposal (Word Count = 251, Student Number = 999877)

Declaration – I Colleen McCulumb confirm that I have carefully studied all the Workbook references in constructing this proposal and that what is described here is a new work and is not copied from any source.

1. Title – Phishing – Preventative Measures

2. Problem – Phishing is identity theft using email where a personal message seeks confidential or private information from its recipient whilst posing as a legitimate request. The intention therefore is to fool the recipient of the message into releasing information which can subsequently be used for fraudulent purposes.

3. Real-World Target - Increase the awareness and generate competence of computer users in identifying and dealing with the nefarious activity of Phishing and hence help prevent identity theft occurring and therefore reducing cases of fraud.

4. Project Outcome – my expected form of outcome will a protocol to use (including examples) in the event of a Phishing incident occurring. The protocol is essentially a set of careful guidelines for use in governing what to do and how to communicate in various circumstances in the event of an identified Phishing incident.

5. Actor – it is expected that these strategies will be used by individual employees both to inform and guide them in recognising, dealing with and reporting phishing incidents.

6. What (interrogative) action protocol (outcome) can be devised for use by company personnel (actors) who use email operationally to ensure that phishing incidents (problem) can be identified, managed and reported thus ensuring that confidential information is safeguarded (target) by profiling identifiable phishing events (spotlight)?

Appendix D – Submission Check List for Assessment 1 Part 3

This form must be included as an appendix to the Assessment submission of the short literature review and specification and it is intended to show you that you have correctly formatted your work and included all that is needed. If you are unable to tick every box then your work is not ready for submission.

Word Count		The maximum permitted word count is 2,500 excluding project plan and reference list.
1.		I understand that every departure from the check list requirements found in my work will incur an overall 2 mark penalty
2.		I have sent the Ethical Examination Questionnaire as a separate document named with my student number to the tutor.
3.		I have sent a letter of support from the organization where I intend to collect data to the tutor by email (Appendix F)
4.		I have written down the word count and it does not exceed the permitted value
5.		I have include a short literature review as required
6.		I have included a specification as required using the exact format of headings found in CN.002 Release 3.3 section 3.5.2
7.		The first page uses the 3 heading lines shown on the specification sample in CN.002 Release 3.3 section 3.5.2
8.		I have used the correct margins of 2cm top, bottom, right and left
9.		The work presented is a single A4, MS .doc format file using portrait orientation (project plan may be in landscape)
10.		I have not attached an cover/front sheets or contents lists.
11.		I have used Arial narrow font at 12pt size except in the project plan, reading list and page footer where I have used 10pt.
12.		I have used a line spacing of 6 lines/inch
13.		Pages have centred footers in the form – Page 1 of 5 - J.J. Letto HEMIS No. 567543 Submission Date: June 2007
14.		I have not used page headers
15.		All main text is right and left justified
16.		Headings are NOT followed by a blank line
17.		Headings are in the same font as the main text but are shown in bold
18.		I have used a blank line to separate paragraphs
19.		I have not numbered any paragraphs or sections although but the set of objectives is numbered sequentially.
20.		I understand that indented sentences can be used where appropriate but bullets are not to be used
21.		The submission file is named with only my HEMIS No. (if anything else is added your file will be automatically deleted)
22.		I have sent my personal profile to the Research Methods tutor
23.		I have sent my induction checklist to the Research Methods tutor
24.		I have looked up and studied ALL the Workbook references mentioned in this assessment
25.		I have included all citation sources used in my work in my list of references
26.		My short Literature Review is not be made up of just quotes and paraphrase but is an evaluative topic area dialogue
27.		I have cited other people's work properly using the Harvard APA format
28.		I have included a references list of at least 10 literature sources
29.		My reference list contains no more than thee books covering Research Methods and Statistics
30.		I have only used the citation form (Briggs 1999) for passing references to texts
31.		I have included at least 3 sources covering the core topic area of this research
32.		In the reference list no more that 3 are internet based
33.		The specification includes a plan to get original data (primary data) and I do not have that data already
34.		I have ensured that the primary data collected can be used to generate a Strategic Business IT outcome of some kind.
35.		My data processing design will generate the stated outcome and the design is clear enough to be executed by anyone
36.		The project has a significant learning potential in the IT/computing field
37.		Plagiarism Declaration - I confirm that the enclosed written work is entirely my own except where explicitly stated otherwise. I further declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions.

Appendix E. Project Topic Ideas

The following list contain some ideas for Projects – it is not intended that you have to choose one from this list they are just to give you a flavour of what you might look at. The list below was written as general ideas but they could always be applied to a particular situation as well.

The first table below is specially designed for those who are unemployed and on this course it is perhaps a little more difficult to find a project idea for the simple reason you cannot easily get access to primary data. So here are a few ideas that you might find useful.

Community – we all live in communities of one sort or another such as: connected to the Church, the Mosque, various clubs, societies, charities and so on. Now it turns out that often students can find a project idea here if they care to look.

Small Business – it might be possible to look at some aspect of small business operation in you community.

Public Services – it might be possible to get permission to work within support organisations run or sponsored by public services.

Internet Products and Services – there are lots of services now that one can access: Radio stations, TV stations, songs and other recordings, diaries, blogs, information sites, online back up and so on

Project Ideas for the Unemployed or those not working directly in IT	
1	Use of the Internet by the unemployed
2	Home shopping and customer services
3	eMarketing for the small business – A linked retail community
4	Internet use by the Immigrant Community in London – Finding Government Services
5	Internet use for language learning in the Immigrant Community
6	Internet use for the teaching of women in closed communities
7	Internet café style services in local libraries – a business case
8	Security practices in Internet cafes
9	Instant Messaging – Is there an Ideal System for personal use?
10	Front Desk Operations in Battersea Swimming Club
11	Ethical considerations in free web access
12	The use of IT in the care and support of the homeless
13	Kiosk technology in Shopping centres – a retail support tool
14	A business case for web based advertising for the small business
15	A review of email providers for private users
16	A review of sponsored links in personal email services – useful or useless?
17	The ethical underpinning of email sponsored links
18	The business case for sponsored links in email
19	A review of the effectiveness of SPAM control in popular personal email systems
20	Online games and the business case for associated sponsored links
21	Gaming machines and the ethics of constant online updating
22	Business Blogging and Uses
23	TV down load Software and the customer supplier relationship
24	Private Web sites - their role in promotion (such as concerts, clubs, etc
25	Web based Special Interest groups and business ethics
26	Use of web bases desk top tools – boon or menace
27	A review of web based diary systems and their business potential
28	Internet Telephone services and their impact on business communication
29	Automatic Online Backup for the private user – A technological and cost effective Idea

Security	
1	Anti-forensic tools (eg Evidence Eliminator)
2	Anti-spyware – a business and personal necessity
3	Awareness Training on Internet Perils for Company Staff
4	Beware of online risks – enterprise users engage on riskier online behaviour than home users
5	Business Skills needs of IT Security Officers in Organisations
6	Comprehensive IT Vulnerability Management
7	Cyber spying
8	Data: Lost, stolen or strayed (off site backup storage for tapes etc)
9	Domain name crime
10	EPS (End Point security)
11	Forensic IT an Essential Business Resource
12	Forensic Tools (eg Windows Washer, Privacy Suite etc)
13	Hackers – Looking for fortune not fame
14	Illegal Downloads and business risk/costs/integrity...
15	IP based surveillance systems
16	IT Security Management and its Impact on Business success
17	Organisational benefits of security surveillance
18	Password Overload and Business Security
19	Protecting the desktop
20	Replacement of names and Passwords – What are the security and Usability Implications
21	Secure ID Applications
22	Security – the users is his own worst enemy
23	Security in Kiosk installations
24	Security Software Interfaces and personal freedoms
25	Security Violation Reporting – How Management Deals with This huge Volume of Data
26	Storage Security
27	The Ethical Hack – A framework for business Value penetration attacks
28	The Insider- Fighting the Enemy within
29	Usability and its trade off with security
30	Usage patterns in Kiosk installations
31.	RFID tagging (on people or staff in airports, shopping centres etc)

Project Management	
1	Analyse, plan, evaluate or report on an IT Project
2	Computing Industry standards and their impact on business
3	Configuration Management Software in large scale IT installations
4	Define the role of ILS in a commercial sector IT procurement programmes
5	Desktop Lifecycle Management – A new MS Provision
6	Ensuring the IT projects Deliver Business Results
7	Explain the implications of ILS usage in IT installations
8	How important is user acceptance in the utility associated with IT systems
9	How IT can help with Life Cycle logistics in asset Management systems
10	IT and Logistics Management
11	IT Project Management Practice could be improved by the Use of Emotional Intelligence
12	Life Cycle logistics in IT systems
13	Managing IT system Integration
14	Report on commercial applications of ILS techniques or philosophies
15	Software Portfolio Management – The Proving Model
16	Software risk management and its implication for IT strategies
17	The requirements gathering process is a major cause of project Management Failures
18	The role of prototyping and user involvement in requirement gathering and proving
19	The role of user training in Requirements gathering

IT and Corporate Managements	
1	Business Advantages of Sarbanes Oxley compliance
2	Business Costs associated with Sarbanes Oxley compliance
3	Compliance – an IT nightmare
4	Cyberslacking and corporate performance/losses
5	Developing a corporate Strategy for Document and Information Management
6	Flexible Working in IT – A way Forward
7	Gaining the business edge with IT
8	How company policy drives IT system selection
9	IS Management in the SME/large corporation/government etc
10	IT Strategies and External Business Factors
11	Management and IT Potential
12	Managers Manage but Technology Enables
13	Managing a business in and IT dominated world
14	Personal gadgets and Illegal Downloads – The curse of Organisations (iPod etc)
15	Strategies for Sarbanes Oxley compliance Implementations
16	The adaptive Enterprise (that is growing IT as it is needed)
17	The changing role of the IT professional
18	The characteristics of a Modern IT manager
19	The effect of company Policy on IT procurement
20	The effect of IT systems on company Policy
21	The Organisational Burden of Software Licensing Schemes
22	The role of IT as a strategic Business Resource
23	The Role of IT Certification in Implementation Strategies
24	The Role of IT Certification in Systems Operational Performance
25	The Role of IT Certification in terms of Strategic IT Development
26	The strategic Role of IT in business is Questionable

Email and Personal Communications	
1	Dealing with email enquires in large corporations
2	eMail - a Business Nightmare
3	eMail and ISPs
4	eMail and the personal user
5	eMail currency and its impact on personal productivity
6	eMail storage Systems and their impact on business
7	Mobile email – Taking a business Lead
8	Phishing – a personal tragedy and a corporate nightmare?
9	Skype and its use as a viable business communication suite (and other similar systems)
10	SPAM – An analysis of common content
11	SPF (Sender Policy Framework) An Answer to SPAM
12	The impact of Spam on personal productivity
13	The role of eMail in a modern business Organization
14	Then effects on business of organizations such as SPEWS in limiting SPAM

Teleworking and Telemedicine	
1	Telemedicine
2	Teleworkers and their Impact on IT security, business success, outsourcing etc.
3	Teleworking and IT professionals

IT Risk	
1	Business Continuity Planning – A Replacement for IT Disaster Recover
2	Critical Incident Management in IT
3	Improving the Application of IT related Risk Management
4	IT and Business Risk
5	IT Infrastructure and Business Continuity Planning
6	Managing business Continuity planning with highly integrated systems
7	Possible cost-based processes as critical management tools with regard to IT

IT in Finance	
1	Electronic bill presentment and payment
2	IT and Micro loans in Developing Countries (Grameen Bank and such things)
3	IT hardware – A never ending Cost Centre
4	Making better IT Investment Decisions
5	Micro Payments a route to a cashless society
6	Small Business Accounting Software
7	The effect on Profitability of implementing an IT supported Asset management system
8	The impact of IT on financial service provision has been significant.

IT Training	
1	Company policy on IT training affects user acceptance of IT system
2	IT training issues and the disabled workforce
3	The role of IT training in ensuring personal productivity

Technology	
1	Content Management systems and their place in a Modern Organization
2	Digital Paper – A new Business Tool
3	High Speed Broadband – it business impact
4	High Speed Broadband and User services
5	How new technologies related to location commerce might affect business policies
6	Keyboards and their Impact on system productivity
7	Optimising business functions by sourcing new Information technology
8	PDA Revival – Is there a Business Future?
9	Portable PCs and their business future (ie blackDog)
10	RFID in a retailing Context
11	RFID in Baggage Handling
12	Screen reading Software Efficacy as a solution to enable the visually impaired to use business software
13	Software Agent Technology and it use in improving web applications
14	Software Agent technology and its future role in mobile computing
15	Software agent technology and its role in improving search engine performance by profiling usage.
16	Sourcing New Technology for enhancing business success
17	Speech recognition system increases wider participation rates/increase worker productivity/ etc
18	The Effect of dual or triple core processors on worker productivity
19	The Paperless Society – an impossible dream?
20	Ultra Wide Broadband – and its impact on business
21	Web Based operating system – Is there a future?

Storage and Data Manager	
1	Data life cycle management
2	Entry level SAN and the SMB/SME
3	ILM (Information Life Cycle) – Controlling the Data Mountain
4	Modern developments in integrated storage management
5	Modern Societies Dependence on Electronic Storage
6	SAN and Continuous Data Protection
7	Storage Area Networks and their Impact on Business Policy

Ethics	
1	IT and its role in Social Inclusion
2	IT ethics and the economy/business
3	IT professionalism is essential for the full development of the industry
4	The effect of Ethical decision-making in the implementation of a Business Information System.
5	The Role of Ethics in Systems Analysis
6	The role of Learned Societies (eg BCS) in ensuring professional Competence
7	Who owns the Internet – A big Company Takeover
8	Copy write protection for online trade marks

Integrated Systems	
1	Attempting to integrate all systems in a company is unwise
2	Highly Integrated systems such as SAP increases worker commitment
3	Highly Integrated systems such as SAP increases worker stress
4	IT/Computing standardization of systems and the impact on business success
5	IT/Computing standardization of systems and the impact on business policy
6	Legacy Data and BI Tools sets
7	Leveraging Data and BI tools sets
8	Lightweight Enterprise Architectures - a way forward in cost control
9	Microsoft Dynamics – A challenge to SAP and Oracle
10	Migration Practices for Legacy Systems and Business Planning
11	Modern HRM systems have had a major impact on recruitment and retention of staff in large organizations.
12	Service-Oriented Architectures (SOA) – A new breed of Applications
13	Taking a cross-organisational approach to IT
14	The impact of IT on global manufacturers

General IT Products	
1	Blog Monitoring – A possible business Strategy?
2	Blogging – A possible business Strategy
3	Blogging – Is gagging bad for business
4	Business implications of the Web Bases OS
5	Implementation and training for BizTalk or Sharepoint Portal Server or Content Management Server etc
6	IT Collaboration Tools and Business Success (email, Intranets, shared files, desktops, user profiles etc)
7	Microsoft Office Business Scorecard Manager – A modern Management tool
8	Modern Software Development and its role is helping the disabled IT professionals
9	Optimisation of IT services (eg HP OpenView)
10	Search Engines and business Efficiency
11	The next wave – Computer Systems that never Fail
12	The next wave – computers that think like humans
13	The role of BizTalk or Sharepoint Portal Server or Content Management Server in business success
14	Voice activated input system and their efficiency in business situations (such as Via Voice)
15	Voice activated systems – a productivity tool
16	Web 2 a new model of usage
17	Web based desktop tools and their use in business
18	Web Services – The future for distributed systems (.NET and J2EE etc)

Document Management	
1	Document Management and support for Critical Business processes
2	Document Management Strategies
3	eBooks and Readers – their use by business
4	Electronic Documents and Record Management
5	Strategic Issues in Document and Information Management

Theoretical Issues	
1	IS needs must be matched to value in that IS systems can only be successful if there is a causal link to business success.
2	IT Application and Organisational Change
3	IT needs to be at the heart of all business plans
4	IT reporting functions and Business Instinct
5	Knowledge Management and its place IT planning/procurement/success etc
6	Mobile Technology Offers Staff a more satisfying work-life balance
7	Results oriented approach to the UI (instead of command-oriented – see 2006 MS office 12)
8	The Evolution of the Intelligent network and its business impact
9	The role of emotional intelligence in IT user support
10	The role of Web Content Accessibility Guidelines in moving web sites into the modern era
11	Trends towards shared resources on the Internet – A business Strategy

IT Services	
1	eAuction - The Future of Procurement?
2	Enterprise permeability and the supply chain
3	Impact of IT on international supply chain management
4	Improving Best practice in IT support units
5	Insuring IT based data assets and certification needs (BS 7799 ISMS)
6	IT Service Levels Agreement and Business Strategies
7	IT Service Management and Business Success
8	Outsourcing Document Management
9	Cause Related Marketing and the Necessary IT infrastructures
10	Software Maintenance – A company wide strategy for business support
11	Vendor Service and Software Licensing

Miscellaneous	
1	Community Technology Previews – A Marketing Strategy or a genuine attempt to communicate
2	Cyber Café – A world of Business
3	High Quality IT systems increases worker commitment
4	Reliance on private computer systems increases the costs of worker stress
5	The computer gadget market and its impact of Business IT
6	The Extended Enterprise (networks of suppliers, eProcurement etc)
7	The impact on worker productivity/morale of removing all personal systems
8	The IP enabled Economy

Appendix F – Sample, letter of support format

All projects require a letter of support to confirm that the data being collected is new. The letter must:

1. Be on headed note paper and signed by a person in authority within the Company/College. Their name must be also stated in full as well as their status or position.
2. The letter(s) is to be scanned in colour and the image attached to the submitted Assessment 1a Part 3.
3. A typical wording would be as follows. However, the company/college may choose their own wording or add extra sections as they please.

Company Format

This format is to be used when your research project is based on gathering data from an organisation. This format is the norm. If you are using more than one organisation then you must supply a letter from each one unless you are using a large number, in which case you must use the College format.

Dear Sir,

Re. Mr Victor Chow. Project: Planar Similarity – A new Synthetic Software Metric

I confirm that the named student is carrying out research at the above named company and I further understand that this research is part of the assessment to gain a Master's qualification. The work proposed by this student is new and I can confirm he is not using any pre-existing data.

The student has explained that the University will regard all data and results as confidential and it will only be made available to University tutors and the External Examiner and will not be published in any public forum without our full written company consent.

Any enquiries relating to this letter should be addressed to Dr Chin Wong of 0986 34571 or via email at chin.wong@ace.org.

Yours Sincerely

Dr Chin Wong

Technical Director (New Products Division)

PgD College Format

This is the format to be used when your research project is based on gathering data from where there is no obvious organisation involved. This is expected to be the exception rather than the norm.

Dear Sir,

Re. Mr Victor Chow. Project: Planar Similarity – A new Synthetic Software Metric

I confirm that the named student is carrying out research on the above named topic and I further understand that this research is part of the assessment to gain a Master's qualification.

I have checked the student record and questioned him about previous project work and I am assured that the work proposed by this student is new and does not use existing data and that this is representative of a new project idea.

The student has explained that the University will regard all data and results as confidential and it will only be made available to University tutors and the External Examiner and will not be published in any public forum.

Any enquiries relating to this letter should be addressed to Dr Philip Ling of 0986 34571 or via email at p.ling@ace.uae.org.

Yours Sincerely

Dr Phillip Ling

Director of Studies

1. WORKBOOK 1. MASTER'S PROGRAMME OUTLINE

The Master's programme has two units of study: Research Methods and Project and the online programme notes together with this workbook pack cover all the information you need to complete it.

1.1 University Expectation

The University expects that when students submit work it is the very best they can do. In practice this will mean several things and all of them will be examined when work is assessed.

English – written English must be of a Master's standard and that means an IELTS score of at least 6.6 (or equivalent) is needed. If submitted written work is judged to be below this standard, students will NOT be allowed to progress to the project stage no matter what their actual language certification states.

Structure – work must be well structured and coherent. In practice students will most often work with a pre-defined set of headings and they must be used explicitly without deviation in their implied content.

Preparation – good work can only be produced if there has been adequate preparation. This will mean a thorough study of any and all references and exercises. Study does not mean a quick read through the notes or academic arrogance which says "I don't need it" or "I know all this stuff". This preparation also means working through the topic idea for your project itself so that one becomes expert in a particular field.

Instructions and Guidance – all the work you submit will have to meet various standards in terms of layout and format and students are expected to follow such guidance diligently.

Using other people work – all work submitted must be the student's own but within that work they may refer to the work of others but all material used must have proper attribution. Thus, if another author's work is copied, paraphrased or summarised it must be properly cited. Students need to understand that paraphrasing (putting things in your own words) and summarisation will amount to plagiarism if not properly attributed. This is a very serious matter and the rule with regard to copying is very simple. If 6 or more words are copied then the sources must be cited and if 10 or more words are copied without attribution then that is regarded as proof of plagiarism

Student's Own Work – the submitted work must be entirely constructed by the student and to do this it is necessary to weave into one's own ideas and thoughts the work of others. One may use the work of others to lend support to a proposition, or to include a definition or an explanation and so on. In other words it is not so much a question of how much of another person's publication one uses but what one does with it in constructing one's own research work. In short scholarship is acknowledging and using the work of others whereas plagiarism is using the work of others and in so doing attempting to fool the reader into thinking it is one's own.

Respect – when writing one is doing it for another person to read and it's therefore a grave sin in those circumstances not to offer the very best one can produce.

Need - only quote, paraphrase or summarize when it clearly adds to what one is saying and it is not just common knowledge or obvious. The key task is to formulate one's own ideas, in one's own words by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

1.2 Overview of Unit Assessment

The two units: Research Methods and Project are assessed separately and students must in each one gain at least a pass grade in order to qualify for a Master's award. The assessment artefacts are.

Research Methods Unit (15 Credits)

The Research Methods Unit will be taught over approximately 12 weeks and assessment details will be published to you early in the Unit. The assessments will be to provide project specification plus a short literature review

Project Unit (45 Credits)

The Project is an extended research exercise where students will be guided by a personal supervisor. For students who have passed assessment 1a, approved projects will start a few weeks after the end of the Research Methods Unit and last for at least 18 weeks. There is only one assessment and that is to prepare a project document based on the specification developed in Research Methods Assessment and is required in the Project itself can be found in Workbook 9.

1.3 Research Methods Unit Assessment Overview

This unit of study requires about 150 hours of effort from each student and will cover research principles, research ideas, research techniques as well as statistics. Assessment details and due dates will be made available early in the study period for the Unit in WebCT. It is essentially in two parts as follows.

Project Proposal Approval – when the Research Methods unit begins students need to gain approval for a project title/idea. The university will supply a list of ideas or students may bring one of their own as long as the related project outcome has a strategic business IT dimension, it is new work, it involved learning in IT and it is a Master's level activity. In the approval process students have to write a short submission to a set format and send it in a plain email to the Research Methods tutor whose decision is final.

Approved – the submission, whilst not necessarily being perfect, meets all the above project criteria and the outline is judged good enough for the student to begin work on the specification. About two weeks after approval is granted a supervisor will be allocated who may assist you in finalising the project Specification.

Permitted – the submission has a suitable idea but its construction is judged to be of poor quality but the student is given the benefit of the doubt and is expected to make good in the specification. No supervisor will be allocated and final approval will be depended on the quality of the final specification.

Rejected – the work is received after the due date or submission does not meet the criteria for a project in this degree and a new topic must be chosen and a new application made. Most often this is because there is no Strategic Business IT, the project research is regarded as trivial or plagiarism is detected.

Short Literature Review and Specification Approval – based on an approved or permitted project proposal students prepare a short literature review and full project specification which must be posted into a WebCT drop box on or before the assessment due date. The Research Methods tutor will review the work and write a feedback report for each student. The specification and feedback report will then be placed before a University panel who will decide whether it is appropriate for a Master's level project. At the end of the specification approval process one of four outcomes is possible:

Pass and Specification Approved – students who obtain a Research Methods pass will be allocated a project supervisor. The supervisor will be automatically sent a copy of the feedback report and specification. Approval will not mean that a specification is perfect and it is expected that students will take note of any feedback given by the Research Methods tutor or the allocated supervisor to further refine it.

Pass and Specification Conditional Approval - students who obtain a Research Methods pass will be allocated a project supervisor. The supervisor will be automatically sent a copy of the feedback report and specification. Conditional Approval means that there are some significant concerns that must be addressed before work begins and students are expected to redraft their specification, based on feedback given by the Research Methods and in discussions with the allocated supervisor.

Fail and New Topic – this means that a student specification has been rejected in its entirety and another topic must be chosen and work must begin again by seeking approval for the new topic before writing a new specification for submission in the next available cohort. This action is most often used when the University decides that the work is trivial, or the work has no significant IT content, or the student has submitted a specification without gaining approval for the topic, or plagiarism is identified.

Plagiarism is Identified – no result will be confirmed and no approval is given and the relevant student work is subject to review by a disciplinary panel. Plagiarism is a form of deliberate deception in order to gain advantage and will always be treated with the utmost seriousness and may even result in students being dismissed from the course.

1.4 Assessment - Master's Project

This unit of study requires about 450 hours of effort, guided by a University appointed supervisor and based on the specification developed earlier in the programme. The actual project document must be supplied in the form shown in section 9 of these notes and is expected to be of about 15,000 words maximum (excluding appendices).

Once allocated a supervisor, students will be asked on what date they wish to submit their project. The only rule regarding project activity is that it must last at least 18 weeks and no more than 1 year but it will be a matter for students to negotiate with their supervisor and the University to agree a submission date. Students are allowed to make small changes to the specification during the project process but they must be approved by the supervisor and must not amount to a change of the topic that was approved.

2. WORKBOOK 2. RESEARCH METHODS CHAT AND STUDY PLANS

This is a general plan for study where chat sessions are important because they are collective and interactive and typically focus on just one important feature of research and to get the best out of the course students need to prepare for them properly: reading the notes, studying the samples and exercises and multi-choice tests that go with each notes chapter, the Workbooks and contributing if you can to the discussion boards.

2.1 Contact Mechanism

Contact with students is through email, discussion boards or chat. Email is very important and you should ensure that you use an Internet based service so that you can get mail almost anywhere. It is not recommended that you use a work-based email account as these are often tied to a location and in any case its not regarded as professional to get course email mixed up with you work ones.

It is good practice to create an email account just for the duration of the course and a common choice is GoogleMail because the storage space is, for all practical purposes, unlimited. If you are not able to create a GoogleMail account let me know and I will send an invitation to you. It is important that only ONE email account is used for communication and that address is made know to the Research Methods tutor as follows.

Whatever, mail system you use it is advisable to set mail forwarding from both your WebCt accounts to your personal one to ensure that you get mail as soon as it available. It is also useful if students have a Skype or IM account as many tutors allow direct access if they are online. Skype is preferred since chat, voice and video are all catered for and during contact one does not get bombarded with advertising. Internet email services vary considerably but my recommendation is that you only use a service that:

- Provides a virtually unlimited storage capacity
- Guaranteed to work from almost any location: hotels, airport, etc
- Allows you to set a mail forwarding address (most services do not so check this with care)
- Provide quality SPAM filtering, virus checking and is not on the SPEWS blacklist
- Has an https:// internet address starter (also shown with a yellow lock at the bottom of the screen)
- Allows POP redirection (so you can use Outlook and send from databases etc)

2.2 Complete Study Plan

Students must work in a committed way for the 12 weeks during the Research Methods unit and submit the work required on the set dates – there will be no extensions given other than for sickness or other indisposition (in which case students need to complete an ECF and provide documentary evidence of incapacity). Failure to deliver on time without permission will mean that the student unit result will be recorded as a fail. For the whole course the timings in hours are approximately as in the following tables:

Course Element	Time	Comments
Chat Sessions	25	Including preparation and summarizing the chat log
Regular Visit to Site	25	For email and discussion board
Study Notes/Text Book	35	Including making notes and doing the tests
Preparing Submissions	65	Including reading the relevant workbooks and topic details

Table 1. Overall Research Methods Unit Study Plan

2.3 Recommended Timings for Completing the Research Methods Work

Look at the following list of times for preparation and plan a way through this unit using these estimates.

Course Element	Time	Comments
Literature Searching	10	The key to a successful submission of the assessments is that ones mind is fully prepared with all the knowledge needed.
Proposal	10	Here students prepare a project proposal: presenting problem, target, outcome, actors and Research Question. The format used for this can be found in the Assessment description
Research Plan	10	Here students prepare a plan for collecting primary data. This is not literature searching, it is new and original research
Short Literature Review and Project Specification	35	A partial short literature review and comment is provided in Workbook 4. The Project Specification format is presented in Workbook 3.

Table 2. Coursework Submission Plan

2.4 Recommended Five Week Development Plan

In this course students must write a project proposal as soon as possible using the format set out in the Assessment papers. However, the basic project idea must be developed and refined carefully and typically it will be done in the sequence shown below where items in blue are specific to Engineering and items in red specific to study projects. Typically this refining process starts in week 3 of the course

There is NO short cut in this work and the standards are very high. The expectation is that you will read and study the notes, examples and exercises with dedication and care. Failure to study with care is usually obvious in the quality of the work presented, so work hard and think through carefully all the steps below – there is NO substitute for thinking your own idea through. There are plenty of examples to guide you but these examples are not templates they are there to help you gain understanding and not as some sort of quick fix to the work.

Topic Area Research – this is about thoroughly understanding the topic area in which your problem is set. For example, if one was looking at Inventory Management using IT in a fast moving retail environment that is where your literature research efforts are to be directed. So one would look at inventory management itself, warehouse based systems, shop shelf systems, POS systems, tracking fast moving but small value items, restocking, forecasting, re-ordering and so on. The idea is that you take time to think of all the aspects of the topic and then you try to become knowledgeable in them. There is no short cut here and the work must be done thoroughly and with commitment.

Presenting Problem Definition – every project will be based on a real-world problem of some kind. Students must define the problem as accurately as possible but the intention is to have just ONE problem definition. (See Workbook 6 section 6.2 and 6.11)

Target – this is what real-world effects will be observable if the problem can be solved. For example, the problem might be about accuracy in inventory records and that would imply that if we can find a suitable project outcome, such as a training plan, that can be used to alleviate that situation then it will result in the target of for example reduced inventory costs. (See Workbook 6 sections 6.3)

Theorizing based on the problem Theme – here one theorises about possible causes of the problem and corresponding solutions. In the case of inaccurate inventory records we might theorize solutions as being based on: production of a training plan for staff, feasibility report on possible use of technology, development of a sales policy and so on. (See Workbook 6 section 6.6)

Project Outcome Form – during theorization one chooses what might be regarded as a best solution route and this becomes the single outcome intended for a project. For example, if we take the problem mentioned above of inaccurate inventory records then a project outcome could be a feasibility report on the use of RFID as this might be seen as a way of solving/partially solving the stated problem. In Engineering projects the outcome will be an application of some kind and that needs to be described. (See Workbook 6 section 6.4 and 6.11)

Actors – once we have an acceptable outcome we must link it with a situation actors. That is we must say who (persons) will use the outcome and how they will use it to get the stated target effects. (See Workbook 6 section 6.5)

Research Question – here one tries to encapsulate the problem definition and one's outcome theorising into a concise and lucid question that will form the focus of the research effort. (See Workbook 6 section 6.8).

Research Design – this is the core of any project and it is the place where one expects to see serious and consistent thinking about how the presenting problem is to be resolved by collecting and processing primary data in order to generate the expected project outcome that will eventually lead to a real-world effect or effects called the project target. (See Workbook 3 section 3.3.6 and either 3.5.1 or 3.5.2 as appropriate)

2.5 Critical Reflection

Students must expect to go back and forth over their work because as knowledge and understanding grows one will inevitably see that some of one's earlier work was incorrect or not as clear as it could be or maybe it can be improved in some way. This revision strategy is very important as a common fault with research work is that it often lacks consistency because there was no serious reflection on earlier work.

2.6 Chat Session Profiles

The following is a simple guide as to what students will be covering in the online chat sessions. These sessions are extremely important as they are usually interactive and are based on using examples. The Research Methods Unit will involve a chat session roughly once every week – half these sessions will be based around the notion of research methods and half based on statistical processes.

2.6.1 Chat Session 1 – Setting up a Project?

The chat will focus on the idea of a presenting problem, target, outcome and actor as the basic project building blocks. From this the chat we will move to discuss a framework to surround a research project and a look at the notion of primary data and some of the core techniques that must be mastered. To prepare for this chat read Workbook 1 and 2 and Workbook 6 section 6.2 to 6.7.

2.6.2 Chat Session 2 – Refining a project Idea?

This chat will take the form of a discussion on how a project idea is explored and focused and a full example will be used followed by an open discussion and questions from students.

To prepare for this chat, students should be familiar with the title approval format shown in the Assessment papers and the specification examples and notes shown in Workbook 3 sections 3.5.1 and 3.5.2. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea. Of particular concern in this chat is the notion of presenting problem Workbook 6 section 6.2 and form of answer (project outcome) in Workbook 6 section 6.4 and 6.11. Students must work hard on these three ideas if they are to form an acceptable project specification.

2.6.3 Chat Session 3 – Problem Solving Method and Research Designs

In this session various problem solving idea will be explored from the most general to models that are focused on particular type of problem areas. Within these models we shall discuss the notion of what data might be needed to answer a research question and how that notion must be focused. To prepare for this chat students should be familiar with the title approval format shown in the assessment and have studied the specification example shown in Workbook 3 sections 3.5.1 or 3.5.2 as well as the associated notes in section 3.1. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea.

2.6.4 Chat Session 4 – Literature Reviewing and Working in a Scholarly Manner

In this session some examples of student work and how they write down their ideas will be examined based on scholarly principles. This will be followed by looking at a process that applies equally to what one writes and what one reads. The remainder of the chat will examine several excerpts from student work that exhibit common faults. To prepare for this chat read Workbook 8 on citation styles and bibliography, chapter 4 of the notes and Workbook 5 and it might be useful to read through the sample short Literature Review in Workbook 4. In addition, it will be useful if one looks at one's own way of using primary source materials and find some examples that are good and bad.

2.6.5 Chat Session 5 – Aim and Objectives

This chat will focus on how to write an aim and a set of objectives based around a problem definition and a Research Question. To prepare for this session read Workbook 6 sections 6.13 and Workbook 9 section 9.7.3 but also consider one's own project idea and what might be suitable in that case.

2.6.6 Chat Session 6 - Open

This chat will look back over the course and typically review faults that arose out of the assessment of the project specification. This will be supplemented by a discussion as to how various project elements: title, research question and Basic Activity for Generating Data, aim (not aims) and objectives are constructed but focused on the basic Activity for Generating Data.

2.6.7 Extra Chats - Open

For some courses there will sometimes be an open chat on Sunday at 1400-1500 where students may bring their questions, comments, concerns or grumbles. These are useful sessions but only when students come prepared with items that they need to discuss. These are not teaching sessions so the tutor will have nothing to say unless students come prepared with questions and are willing to participate.

3. WORKBOOK 3. PROJECT SPECIFICATION NOTES AND EXAMPLE

This section contains some guidance notes and sample completed project specifications - please consider them carefully. Do NOT copy them blindly – they are just for guidance although the headings to each section are mandatory therefore students must write their own entries under each heading in a way that matches what they want to do. The aim of the specification is to state a complete project plan as clearly as possible so one needs to be concise and precise.

3.1 Project Styles

In projects two styles are commonly found. There are some restrictions on these two forms depending on what programme you are on but the Tutor will advise on that issue. Briefly the two styles are as follows:

Engineering – here you design and build a software application, create a system design etc.

Study – here you design a research program to collect primary data in an attempt to find an answer to an interesting question. For example, one might investigate whether cascading styles sheets lead to simpler accessibility or you might evaluate the role of email management in business success.

3.2 Specification and Design

The following notes and samples for project specifications may help you prepare your own. In summary, one needs to think of the whole processes as starting with a problem definition and ending with a solution (your project outcome) and the element that connects these two things is your research design. It follows that unless you have a good design you will not be able to get from your problem to your outcome and that will mean your project fails.

3.3 Project Specification Headings and Formatting

All the following main headings and subheading must be used and students must not introduce others. As these guidance notes are read it is advisable to also look at the relevant examples in section 3.5 so that one can clearly understand what is being said.

3.3.1 Specification Header

Make sure all your details are entered correctly otherwise work may be misfiled or rejected by the University because we cannot ascertain whose work it is.

3.3.2 Project Title Construction

Project titles must make clear sense in English and not be overlong. See Workbook 6 section 6.14.

3.3.3 Project Task Description

The main function of this section is to explain what is going to be done using the suggested headings below and as shown in the sample. The headings are intended to be precise and if students ignore or change them or use them for any other purpose the work will be rejected. The actual selection of headings will depend on the type of project: Study or Engineering.

Engineering Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct an Engineering project task description and must expect to go over them many times before a concise and useful description is formulated. For Engineering projects please note that a functional description means that one says what the application will do for the users and not how it might be built or what architecture is involved.

Situation Overview – express here a concise and high level description of the existing or proposed application area.

Presenting Problem Definition – a concise definition of some real world problem related to data processing of some kind. This is an important step since unless one can clearly see what the problem is then any solution suggested may be deficient in some way. In most cases the problem definition in engineering projects is related to elements such as data availability, searching, access speed, storage, processing, accuracy, sharing, reporting, entry, updating, deletion, control, security, volumes, segregation, consistency, worker efficiency, process systematization, communication and so on. For the purposes of writing a specification the expectation is that students will focus a problem definition on one major aspect of the application scenario. See Workbook 6 section 6.2 and 6.11.

Real-World Target – a summary of the real world effects that are expected if this problem can be solved or partly solved. (See Workbook 6 section 6.3)

Application Proposal – expressed as a concise description of the main system functionalities. When describing the main functionalities it should be done at a high level and it is recommended that they are all coherent and there should be no more than 10.

Ethical Overview – express here a concise review of any ethical impacts of gathering the primary data, processing it or system usage.

System Architecture – a concise description of the major or main architectural elements of the proposed application

Strategic Value – expressed as a concise argument that the application is able to deliver to the stated problem definition.

Study Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct a study project task description and must expect to go over them many times before a concise and useful description is formulated.

Situation Overview and Problem Setting – a concise, high level description of the context in which the research is set.

Presenting Problem Definition – expressed as a concise statement of the single underlying problem leading to this study. This is an important step since unless one can clearly see and define what the problem is then any solution suggested may be deficient in some way. Study projects look at an aspect of strategic business IT and that might cover technology effectiveness, IT investment, user acceptability, development or improvement plans, feasibility studies, legacy systems and so on. See Workbook 6 section 6.2 and 6.11.

Real-World Target – what desirable real-world effect or effects are likely if the stated problem can be resolved or partially resolved? (See Workbook 6 section 6.3)

Intended Project Outcome, Actors and Data Spotlight – write a concise statement that expresses the expected major project outcome as it arises out of the stated problem definition and your personal theory and would be an answer to the Research Question. See Workbook 6 section 6.4, 6.8.4, 6.11 and 6.5.

Research Question – expressed as a concise question that captures the problem definition and the real-world target along with other necessary features. See Workbook 6 section 6.8.

Ethical Overview – a concise review of any ethical impacts of gathering the primary data, processing it, presentation or usage of results in the form stated

3.3.4 Overall Project Aim

This is a vital point in the specification because in a very concise manner a researcher brings together in one aim: the main project **activity** to get a stated project **outcome** as well as telling us what **data** is the focus of the activity and finally what the purpose or **target** for the project outcome is in relation to real-world problem resolution. It is essential that you fully understand these four elements as described in Workbook 6 section 6.13, 6.13.1 and Workbook 9 section 9.7.3.

3.3.5 Set of Project Objectives

To meet an overall aim it is necessary to achieve a number of milestones indicated by a set of objectives generating minor outcomes. Objectives can be hard to write and it is expected that there would be between 3 and 6 of them. See Workbook 6 section 6.13 and 6.13.2, Workbook 9 section 9.7.3.

3.3.6 Research Design

The Research Design is the core element that generates primary data set and processes it into your project outcome. The Research Design is divided into two phases.

Design for Collecting Primary Data - a process or processes used to define and create a primary data set. It has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the actual data and present that data.

Design for Processing Primary Data - a process or processes used to manipulate the structured primary data set to get the expected project outcome.

A useful analogy for a Research Design is that it is like deciding that you want a sponge cake and then working with a shopping list (a list of primary data that you want) to collect a bag of ingredients (collection of the listed primary data). Once we have our ingredients (primary data) we use a recipe to prepare and mix them (pre-processing the primary data) ready for the final processing step to bake the cake (like generating your form of answer). To reverse the analogy, if you were going to make a cake you would not walk into a shop and just pick up a random set of ingredients and then mix them all together into some muddle, bake it and expect a cake to emerge - no one but an idiot would do that would they?

The suggested headings to use are as follows and you are recommended to use them carefully in a step by step manner to construct a research design. You must expect to go over them many times before a concise and useful design is formulated. In the examples I have added the step numbers for clarity but you do not have to do that in your own work as long as all the elements are present.

Engineering Projects Research Design Format

Research Design Phase 1 – Requirements Collection Process

This phase is concerned with a process that generates a reliable collection of primary data which in an engineering project will be a set of requirements. See Workbook 7 section 7.14.

Define – here one bases the definition of requirements on the outline proposal document.

Location – state where or from whom the requirements can be found.

Collection Protocols – here it is necessary to select appropriate collection protocols such as: interview, observation, records searching and so on needed to collect the requirements under the standard four headings: Functional, Non-Functional/Performance, Technical and Usability. See Workbook 6 section 6.7.1.

Requirements Presentation – the requirements data once collected will typically be presented as interview transcripts, notes and copies of documents and lodged in the project document appendix as a kind of requirements catalogue.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulate it to get a design for the application. This is in two sections.

Overview – show how the various requirements are expressed in a design.

Specific – in any design there will be aspects that have no obvious means of expression and such aspects are typically written as a list.

Study Projects Research Design Format

Research Method – make a selection and write a concise rationale for its use. See Workbook 7.

Research Design – Primary Data Collection process

This phase is only concerned with generating a reliable primary data set and is based on the Basic Activity for Generating Data but to be it has to be surrounded by a complete process.

Activity and Data Spotlight – a concise description of the activity that forms the core of the primary data identification/spotlighting and collection process. It is expected that you will name some primary data items here. See Workbook 6 section 6.9, 6.10 and 6.11.

Location – a concise description of where the primary data may be found. In practice it may come from almost anywhere including extraction from existing secondary sources.

Collection Protocol – a concise description of the actual collection procedure which may be based on one or more of the following: interviews, questionnaires, observation, roles playing, document analysis and so on. See Workbook 6 section 6.7.1

Primary Data Collection Presentation – expressed as a concise description of the way in which the primary data will be presented.

Research Design – Processing and Presentation

This phase is only concerned with a processing the primary data set in order to get the expected project outcome.

Design of Pre-Processing for Primary Data Collection – a concise description of the processes applied to the raw primary data to generate a refined and well structured data set expressed in a fashion that makes it suitable for generating the intended project outcome. (Workbook 6 section 6.7.3) (Please note that this step will not always be needed)

Design for Generating the Intended Project Outcome – here the structured primary data set (pre-processed if necessary) is used in some algorithmic or heuristic fashion to generate the intended project outcome and show that in its final form it can be used by situation actors to gain the target effects.

3.3.7 Literature References

This section is used to assess how well a student has prepared for the project activity. The University will want to see that the reading is current, comprehensive and focused on the topic area. It is expected that work in the specification will be supported from the literature particularly in the outline description and research method sections. Unless the literature is seen to be used in the various sections of a project specification it may not be approved although it is not expected that one cites from every book in a reference list. See Workbook 5 and Workbook 8 and make sure citations are in the Harvard APA style.

3.3.8 Project Planning

The plan must be developed by looking at the outline project document contents list and considering what activities are necessary to generate the various project objects. Aim for around 12 to 20 activities lasting at least 18 weeks with any suitable start date. A project activity is something that is significant and requires planning and monitoring. So for example:

Prepare Metric Program – this is clearly a significant activity that has to be planned and monitored and so properly part of the plan

Select an Organization – this is an activity and might be important but it is doubtful if there really is a significant process involved here that has to be planned and monitored.

Outline Implementation Plan – this is not an activity so should not be in the plan.

The University will examine each plan and will want to see that it is focused on the project – the implication here is that it should be possible to see that a given plan supports a particular project idea not just a copy of one of the samples or is so generic it might apply to any project.

3.4 Testing Your Problem Solving/Research Design

A design must amount to a logical plan that takes a problem definition to a description to the expected outcome that will resolve the stated problem. The following are a useful check that a plan is sound.

Practicality – consider whether one has the resources to be able to carryout a plan. This is a very serious step and must not be taken lightly. It is all very well to have an elaborate plan on paper and to think because it all sounds logical that it can actually be done. In many cases a crucial test of practicality is to be sure that one can get the data from the locations specified.

Credibility – here one is expected to be honest and decide whether the plan will result in useful data and outcome. It is unfortunately true that many research projects end up being trivial because of poor identification of data and more importantly the choice of appropriate collection protocols. It is also worth considering the data processing functions as they must also be credible.

Confirmability – this test is about what would have happened if the same research was done a second time with the same data – would the researcher end up with the same answer. To put it another way, is the processing method too dependant on an individual and that dependence may lead to bias.

Trustworthiness – here we are concerned that the conduct at all stages is such that one could have confidence that the results are genuine and not manufactured.

3.5 Example Specifications

Here are some sample specifications, they are complete except for the contents list and project plans but they are not meant to be copied without any conscious thought and any obvious attempt to do so will result in specification rejection.

3.5.1 Example Complete Engineering Project Specification

Here is an example engineering specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Literature Review & Project Specification (Engineering) – Jan Smith 341387 MSc Computing

Detail - jan.smith@port.com for Cohort Started March 2006 (Word Count = 2,414)

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Intention – the customer is SIS and the application is expected to go live by June 12, 2007.

Project Title - An Assessment Marks Processing Application. (See Workbook 6 section 6.14).

Situation Overview

Currently, the core processing is done by staff members dealing with their own assessment marks, typically using Excel. The staff member then forwards his marks sheets, usually in paper form, to the administration office where the marks are collated using Excel to give an overall score for each student. These two marks sheets: individual unit marks and overall student marks are then presented to the Board of Examiners for scrutiny and acceptance. The process ends when a transcript is sent to each student detailing their results for that semester.

Presenting Problem Definition

The actors feel that the root problem is about consistency and accuracy given the sensitivity of the data but coupled with difficulties with storage, retrieval and reporting. (See Workbook 6 section 6.2 and 6.11)

Real-World Target – the desired effects here are that consistency and accuracy are both improved but at a reduced workload. (See Workbook 6 section 6.3)

Application Proposal

Based on the presenting problem there an application is needed that can offer us consistency and accuracy in the processing of assessment marks, both by unit and by overall student performance. The system to be called a mark processing system and it will have the following main functionalities. (See Workbook 7 section 7.14)

Functional Requirements

1. Store name, address, year of study, name of course and unit details of all registered students.
2. Store the assessment patterns for each unit including weights and pass mark.
3. Allow for the entry, updating and deletion of any or all records.
4. Allow for the entry of assessment marks for individual entry or by batch updating via CSV
5. Report on marks for each unit including basic statistics.
6. Report of overall student performance, including basic statistics.
7. Produce student transcripts.
8. Provision for other ad hoc reports at a later date.
9. Secure access to individual results to be available to students through a portal.

Non-Functional and Performance Requirements

1. Store records for at least 6 years.
2. Allow for at least 6 simultaneous users
3. System must be capable of processing all the data and providing the reports within 10 working days. The estimated current volume is 145,000 data entries and 139 reports but this is expected to grow by about 7% per academic session.

Technical Requirements

1. Be developed in MS Access 2003.
2. For use under Windows XP.
3. All processing activities, including reporting, to be carried out using native Access facilities.
4. All processing is to be done using Access VB and no macros are to be used.

Usability

1. Be developed using normal windows formats and standard colours.
2. Fonts use in screen to be no smaller than 9 point and standardised at Ariel Narrow.
3. Assumed screen size to be 19".
4. Report to be printed as appropriate but with fonts never less than 10 point.
5. Data entry load per screen to be as recommended in DEF 981.90.
6. There should be some consideration of access via the portal for the visually impaired.

Ethical Overview

The collection of requirement here does not present any ethical problems. However, when in use the system contains personal and sensitive data and this aspect must be considered in the design

System Architecture

The intended application is essentially a database system with a web link. It will therefore have two interfaces: one a direct link to the database through the Access application and the other through a secure web interface routed through a portal but with only read access.

Aim

To build an assessment marks processing system using standard MS products in order to ensure consistency and accuracy in the processing of student results. (See Workbook 6 section 6.13 and 6.13.1, Workbook 9 section 9.7.3)

Objectives (See Workbook 6 section 6.13 and 6.13.2 and Workbook 9 section 9.7.3)

1. To produce a detailed, departmentally based, mark processing requirements document.
2. To produce a detailed mark processing database design using standard documentation protocols.
3. To produce a detailed assessment functional design to include data entry, updating, deletion for marks processing and reporting.
4. To design the secure portal for student use based on University entry protocols.
5. To produce and evaluation report of the marks application.

Research Design Phase 1 – Requirements Collection Process

This part of the research design is concerned with constructing a reliable primary data collection for later processing into the form of answer expected. In this case the primary data collection is a set of detailed requirements for the marks processing application. The primary data that we need is related to the proposed major functionalities stated earlier and given to us in the form of a proposal. For each of the functionalities it is now necessary to decide. (See Workbook 7 section 7.14)

Location – The requirements can be found at various locations in Portsmouth. In particular

Detailed Functional Requirements: the appropriate targets for this exercise are: SIS office administrators, departmental course leaders, individual academic staff, Heads of Department and the University registry (for regulatory aspects). It may also be useful to make contact with a number of external examiners to ensure that the reporting arrangements are acceptable. In addition there will be various documents such as regulations and marks sheets

Non-Functional and Performance Requirements: the appropriate targets here are the Registry since they set examination and graduation dates as well as define the necessary reports. The office senior administrator also needs to be consulted for staffing and usage issue. During this process there must be detailed discussion with the department and the Registry over security

issues as this is a major ethical issue. In addition there will be various documents such as regulations, external examiner reports.

Technical Requirements: the appropriate target here is the departmental technical to establish hardware and software profiles. It may also be necessary to discuss network and security issues with the University central computing department. It may be necessary to see network and PC specifications and various security profiles.

Usability Requirements: the basic design is based in Windows protocols so there are no particular requirements to be gathered. However, because it is possible to implement interfaces in a few ways particular usability requirements will be ascertained by use of a mock-up used with the administration staff. With regard to the Portal there will need to be discussion with the University webmaster over formats and protocols to be used. In addition there will be various documents defining standards and formats.

Collection Protocols – The collection is essential a survey format where each requirement aspect will be discovered by just three formats: (See Workbook 6 section 6.7.1)

Detailed Functional Requirements: expressed as interviews, document analysis (marks sheets and regulations) and some observations. It may also be necessary to use observation to examine any existing Portals.

Non-Functional and Performance Requirements: interviews, document analysis (marks sheets and regulations) and observations.

Technical Requirements: interviews and document analysis (system specifications and profiles)

Usability Requirements: interviews and document analysis (system specifications and profiles). In addition it will be necessary to run some focus groups to look at various interface design option by means of mock-ups.

Requirements Presentation – the requirements data once collected will be presented as interview transcripts, notes and copies of documents. These artefacts will be reviewed and a tabular format used to present the requirements and lodged in the project document appendix.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulates it to get a design for the application. This is in two sections.

Overview – here the vehicle used to present the various requirements in a design format will be UML. The mechanism will be to take the written requirements documents and map them to a suitable diagrams in the form of use cases, class diagrams and where appropriate collaboration or sequence diagrams.

Specific - where necessary a written list will be provided. These will mainly be used to state unambiguously the various non function, technical and usability details.

Project Plan

Any clear format may be use but a typical format (but not events) can be found at the end of the Study Project sample specification.

3.5.2 Example Complete Study Project Specification

Here is an example study specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Project Title - Quality Control in Program Development - A Possible Strategy (Workbook 6 section 6.14).

Situation Overview and Problem Setting

The research is set in The University of Portsmouth with the School of Information Systems. In that context it will focus on the programs produced by first year computing undergraduate students.

Presenting Problem Definition

The problem for developers is focused on knowing when code is robust and ready for release. (See Workbook 6 section 6.2 and 6.11).

Real-World Target

The benefit that would accrue in the real-world if this problem can be resolved or partially resolved is that developers can detect potential errors at the code stage and hence feel more confident about their product and therefore not risk costly development overruns and compensation claims from clients. (See Workbook 6 section 6.3)

Intended Project Outcome, Actors and Data Spotlight

It is expected that the form of the answer arising out of this work will be a demonstration in the form of a report with graphical evidence that endorses the proposition that Planar Similarity is an appropriate software quality indicator in that outliers can be detected from application code and in so doing produce an error indication protocol and hence the target effect is gained. It follows that the data spotlight will involve calculating various software metrics from application code and inferring a software defect.

It is expected that the error indication protocol will be used by software developers to pinpoint errors in code and hence guide them in the design of generic program templates and in the testing phase and hence help to ensure that product confidence is heightened and cost overruns do not occur. (See Workbook 6 section 6.4 and 6.5)

Research Question

What (**interrogative**) software error identification protocol (**outcome**) based on use of the planar similarity metric, is available to software development engineers (**actors**) to ensure that software applications are ready for release (**problem**) in order to meet development time scales and ensure client satisfaction (**target**) by examining its efficacy in pinpointing software defects at the code stage (**spotlight**)? (See Workbook 6 section 6.8)

Ethical Overview

There are no current users of the process being developed and at this stage there not seem to be any ethical consideration of importance. However, it is necessary to explain to the students supplying the sample programs the purpose of this study and assure them that none of this information will be used for assessment and allow them access to the results if they so wish. If the target actors use this method then it would possibly expose programmers competences to managers and this may have a negative effects if it is seen not as an aid but as a kind of assessment of their abilities.

Aim

To report (activity) on the efficacy of the Planar Similarity measure using simple metrics as a means of finding outliers in program code (spotlight) and hence reduce coding errors by means of an error identification protocol (outcome) leading to development cost reduction and client approval (target). (See Workbook 6 section 6.13, 6.13.1 and Workbook 9 section 9.7.3)

Objectives (see Workbook 6 section 6.13 and 6.13.2 and Workbook 9 section 9.7.3)

1. To model the application software construction process based on an extensive literature review.

2. To report on appropriate simple and synthetic metrics that might be used as indicators of quality in application programming code.
3. To define a process that will extract the defined metrics for any piece of application code.
4. To document a suitable statistical process for reducing the metric values set to just two dimensions.
5. To analyse and report on the data, including outliers, and hence derive some general conclusions regarding the utility of the Planar Similarity metric and its error indication properties.

Research Design - Research Method

This research is aimed at giving an indication (loosely proving) the efficacy of the Planar Similarity metric within a given context. With this in mind simple experimental procedure will be used as described below. (See Workbook 7)

Research Design: Primary Data Collection Process

This part of the research design is solely concerned with constructing a reliable primary data collection for later processing into the report outcome defined earlier.

Activity and Data Spotlight

The basic idea is to compare a new piece of code with an existing piece that is known to be sound and calculate a series of metrics each one that might highlight any differences and so indicate an outlier. (See Workbook 6 section 6.9, 6.10 and 6.11)

This study will define 20 software metrics which will be calculated automatically for each sample programme. The metrics that form the primary data collection for this research will be such things as: function density, function count, cyclomatic complexity, data associations, decision count, decision density, number of variables, number of function calls, etc. (see Workbook 6 section 6.7)

To set up this experiment three computer program specifications will be drafted with the students working in 'C++'. The specifications will be written so that the defined software application is, in each case, of a different application style and progressively more difficult. An expert in 'C++' will produce a set of generics to match the requested programmes types – it should be noted that a generic is an outline or skeleton of certain kinds or classes of program.

Location – The sample frame is all first year students on computing courses at Portsmouth University. This is around 350 students and my calculated sample size is 200 students, however, since the data collection process is automatic all 350 students will be used in this study.

Collection Protocols – students will be given the application relevant generics and the specifications and asked to write three computer programs of increasing complexity, one in each of three semesters and deposit their completed programmes into a drop-box. This is a large data set and for practical reasons an application will be written that will process each student program so that metrics may be calculated automatically and stored in a suitable electronic file. (See Workbook 6 section 6.6.1)

Primary Data Collection Presentation

The sets of primary data will be available in the project document appendix and will be presented in tables where the rows represent the sample programs (one row for each sample) and the 20 columns the metric values.

Research Design: Processing and Presentation

This part of the research plan will take the whole collection of primary data and manipulates it to get the expected outcome form, which was a demonstration in the form of a report.

Design of Pre-Processing for Primary Data Collection (See Workbook 6 section 6.7.3)

The metric data sets will be read directly from the files produced in the collection phase and then statistically processed to define a similarity measure for each program using principal component analysis and multidimensional scaling. The outcome of this processing will be pairs of values, one pair for each sample program, suitable for plotting in two dimensions structured as a table of results for each program tested.

Design for Generating the Intended Project Outcome

Once the graphs are available it is then a simple matter to look for outliers in particular and attempt to explain their distance and orientation from the generic and other programs in the group by a close examination of the underlying program code that gave rise to it.

The contention is that similar programs will cluster together and ones that are different (even though the specification was the same) will show up as outliers and can be identified and examined to see why that difference occurred. It is hoped that the results will be similar for all three program specification involved and hence demonstrate that planar similarity is effective software metric. Hence, by examining outliers and linking those to code fragments it will be possible to review the results and generate my report on a efficacy and a protocol for error identification. (See Workbook 6 section 3.5.2)

4. WORKBOOK 4 – LITERATURE REVIEW & STRATEGIC IT VALUE NOTES/EXAMPLES

This is a sample of what is expected in assessment 1a, however, it only shows two elements: the strategic business IT statement and the short Literature Review. Try to keep in mind that this is just ONE example and do not try to copy it blindly or try to fit it into what you want to do.

Strategic IT Value

This work was based on trying to resolve or partly resolve the problem of low quality code leading to the need for costly re-work at later stages in the development cycle. The importance strategically of this work is that the outcome: a definition of new software metric will imply that it is possible to identify poor application code and this can be done at an early stage in the software development life cycle. The importance of this is that corrective action can be taken early in the development cycle and as a consequence costly re-work late in the cycle can be avoided or reduced. A secondary or added value element is that the results will allow the identification of good programming standards and this in itself will also lead to improvement and strategic advantage on all products delivered.

Tutor Comment

The key element here is that one relates the expected outcome or form of answer to its use in resolving the problem theme that was the basis of the project, and hence demonstrate a strategic business IT value. Failure to create a clear argument based on the problem theme and outcome leading to a strategic business IT value will mean loss of marks.

Literature Review (See Workbook 5 section 5.1, 5.6, 5.7 and 5.8)

Hiskett in his 1987 seminal paper on metrics defined several apparently useful metrics, the best known of which are 'program vocabulary' and 'program length' which are essentially metrics that count operators and operands and their usage in a given piece of code. Hiskett's metrics are easy to calculate but he was unable to show any strong correlation between his measures and program quality as defined by experts in the field. Similarly, Rogers and Hamerstein tried to use Hiskett's metrics as predictors of MTBF in accounting software but the results were inconclusive and no link could be found between the metrics and the type of software (functionality), accounting in this case, and the metric used.

Garlick, Sheene and Southwood (1999, p450) attempted a new approach that involved the notion of similarity, which they called planar similarity – that is two programs could be defined as similar because: they are written in the same language or they perform similar functions or they were written to the same standards or they are written to the same specification or they were written by the same team or finally they perform the same function. Their work is aptly summed up in the opening paragraph of their paper:

"The nature of any true measurement is easy repeatability and this implies that the style of measurements form a suitable metric space. This means that we need to define the nature of the similarity before we define a measure. In principle this is simple since it is easy to name the similarities but in practice it has been difficult to articulate a precise definition."

The similarities described above deserve further explanation but here only two of them in combination are used: similar language and similar or same specification. Similar language is easy to understand but at first glance it would seem that if two different programs are written to the same specification they are bound to be the same. However, after a little thought, it is obvious that if two different people write two different programs to the same specification the programs are certain to be different in many respects. It follows that the basic, though loose, hypothesis is that if planar similarity can detect a similarity (alternatively difference) in these programs - written to the same specification but by different people - it might be possible to use planar similarity to detect differences between two or more programs against any defined mode of similarity. Conversely, if it cannot be shown that a similarity exists between two or more programs written to the same specification then there is no hope whatever of showing any other kind of similarity with this metric.

Two final points need to be considered: what exactly is meant by software quality and why would a similarity measure be a good indicator of quality? To answer the first question we have only to refer to Kitchenham's 1998 paper where she defined five kinds of quality, briefly:

Transcendent View – quality is a kind of innate excellence, something felt rather than seen.

Product Based View - quality is related to the content/attributes of the product.

User View – quality is seen as equivalent to fitness for purpose.

Manufacturing Based View - quality is equated with conformance to specifications.

Value Based View - provide product at an acceptable price and conformance to a specification.

In this study the transcendent view was the one chosen as the basis of the definition of quality. The meaning of this view is defined by experts in the field – that is, can an expert in, say, Java programming make a judgement as to whether a given piece of code is good or bad – well, here it is argued that such an expert can and does such tasks routinely. Curiously there is very little literature on this idea of expert opinion within the software community but Gavin as early as 1978 touched on the subject. However, it is a reasonable conjecture and it will be used in this study – interestingly, if it can be shown that planar similarity can detect similarity (or equivalently differences) then it would also support the conjecture that experts can judge software quality.

Finally, the study will rely on the ability of experts to judge quality in software. This judgement is exemplified in the production of exemplar or generic programs. Garlick (2003, p98) has written extensively on this subject and the work is well known and will not be fully reviewed here. However, it is possible to define classes of program modules - validation, input, calculation, reporting and so on – it follows, that using the idea of similarity it is useful to create a standard or *generic* program or module for each class. Such a program can then act as a base line for all planar distances related to its application class and hence be a measure of similarity (or difference).

Using Garlick's idea we can let experts define our generic and then use that to compare with other programs – if we declare a difference then in simple terms we need to look at that program because it might be of poor quality and conversely if we declare no difference then we can fairly conclude that the program is sound.

Tutor Comment

The literature review is supposed to be a student's own work. As such it is a discourse that outlines the major elements of topic area but amounts to an essay which is the student's alone. In practice this means that students must read deeply into the subject and then weave what is read into what the student already knows or believes in order to create a useful summary of the topic that will form a strong base for carrying out the actual primary data research - this implies that you 'master' the subject area and become expert in it.

It follows from the above that if all you do is copy or paraphrase from various sources without any significant comment or analysis on your part then it amounts to plagiarism and is worthless.

One final point is that when you write up your review in your final project document you should use various sub-headings and other formatting elements to structure the section to make it readable and meaningful.

5. WORKBOOK 5. LITERATURE REVIEW

The main function of this review is to ensure that one's mind is prepared with all the specific problem area knowledge that it needed to carry out the project and its primary research. In practice this implies the rather difficult task of integrating different ideas, theories and experiences into a thematic, informative, complete and clear discourse on your chosen subject area.

Preparation of the mind is done through adding your own critical evaluative comments and ideas on what you find in the available literature and such critical reviews are typically hard work and not about downloading a few articles from the internet. The key characteristic of the greatest thinkers in history was absolute and unswerving honesty in all their thinking and that principle has never changed. They used their intellect and reasoning abilities to the full. They were honest no matter what the subject be it religious, political, business or academic. These men would not accept dogma from religion, politics or academic sources without subjecting it to serious critical questioning and of course this often meant great suffering for them.

5.1 Plagiarism

The KEY is honesty – without that your work is worthless – you may be able to fool some people but as Shakespeare said “This above all: to thine own self be true, and it must follow, as the night the day, Thou canst not then be false to any man.” So when you plagiarize I may not know, the University may not know but YOU will always know that you obtained something falsely.

Plagiarism means passing off other people's ideas as if they were your own in short it is a form of stealing or cheating. It is fully expected that students will carry out research prior to completing a piece of work. This may include the use of books, journal articles, reports, manuals, notes and so on as source material. The material may be public, restricted to a closed set of people or with a security classification, or privately communicated. The principles are the same whether the material is on paper or in an electronic format. When you refer to an idea in a piece of your own work, it falls into one of several categories:

Common knowledge - many people know it and the information does not belong to anyone person but it cannot normally be deduced by you it has to be learned. It is probably talked about in several sources: the world is round, computers contain both processors and memory, OO is routinely used in software construction and so on. If you are sure that it is common knowledge, you do not need to cite a source. Be careful, authors will often write down in their own work things that are common knowledge so quoting them in that instance amounts to saying that a bit of what is common knowledge actually belongs to that author and that of course is an absurdity.

Obvious – many people know it and the information does not belong to anyone person but it can be deduced. It is probably talked about in several sources: companies tend to grow as time goes on, when the sun goes down it gets dark and so on. If you are sure that it is obvious you do not need to cite a source. Be careful, authors will often write down the obvious in their own work so quoting them in that instance amounts to saying that what is obvious to every one actually belongs to that author and that of course is an absurdity.

Published – this refers to an idea that is found in a specific source or sources which is not common knowledge nor obvious but is nevertheless useful – in these cases you must always cite the source or sources of such an idea.

Original – you may include freely original ideas of your own. However, be aware that if the reader sees an idea that is not cited and is not common knowledge nor obvious, then they are entitled to believe that either it is a new idea published by you or you have plagiarised it. It follows, that if you are introducing idea of your own it is necessary to make that clear by the way it is presented.

5.1.1 Identifying Plagiarism

Plagiarism does not occur only when you copy words verbatim. Plagiarism is about ideas, and even if you express the idea in your own words, you may still be guilty of it if you do not credit the source. However, expressing an idea in your own words might often be good scholarship. The difficulty is that anyone can copy and paste a phrase, sentence or paragraph and cite its source. This is technically not plagiarism, but it's often very poor scholarship since it is obvious that such an activity tells us nothing about the learning, if any that has occurred

Scholarship is about showing your understanding and criticism of ideas. Simply copying, paraphrasing or summarising can show understanding only to a limited extent. You need to “add value”, that is make your own contribution to knowledge, to what you've read and you can usually only do this by expressing published ideas in some way and mingling them with your own thoughts and ideas.

5.1.2 Common Critical Devices

Try to infuse your work with your own thoughts and ideas and let these mingle with what it is you have found in the literature. The most common forms doing of this are:

Interpretation - explaining and expanding on what you have found.

Criticism/Questioning – critically discussing by questioning in order to judge whether the ideas are good or bad.

Decomposition or Analysis – to tease out the constituent parts of an idea.

Synthesis – by means of discussion and explanation link separate ideas together.

Selectivity - showing which ideas to include and which to discard.

Abstraction - taking an overview or defining a model or framework, usually by looking at examples.

5.1.3 Common Literature Tools

The following are the most common means of incorporating, in a scholarly fashion, the work of others into your own written work (a fuller discussion of these tools may be found in the notes).

Copy – use the exact words using quotation marks. A quote may in principle be any length but a good rule is that each quote should only carry a single main idea, which you want to use and then you must introduce it and then follow it up with discussion.

Paraphrase – expressing something that you have found in the literature in your own words - the intention being to simplify, explain, or interpret a complicated idea. But take care there is a very fine line between simplifying, explaining and translating something and just being lazy about adding anything to what you have found.

Summarise – producing a précis or abridgment of a part of the source we have found. Essentially one is trying to capture the main points in an argument or description.

Analyse – the purpose here is to offer a detailed examination of some whole by scrutiny of its parts.

Synthesise – here the idea is to take parts and put them together into a new whole for some purpose.

You might find it useful to remember: copy in order to discuss, paraphrase to simplify, explain or interpret, summarise to capture the main points, analyse to understand and synthesise to build something new.

5.1.4 University Review Assessment

When the University looks at your Literature Review it will be trying to decide if you are committed and prepared for the topic and working at Master's level. If your work is poor in terms of structure, content and form you will find yourself failing. This is NOT necessary so long as you put in the work and ensure you understand how to use citations and the literature. I want to encourage you to do good work - it will ensure that you pass well and it makes your work a pleasure for the Examiners to read.

5.2 Review Content

The review is about your topic area and about you becoming sufficiently expert in it to deal with the problem that you have uncovered. The intention is for you to offer a discourse that is focused, relevant, authored, measured, evaluatory and expressed as a dialogue. (Notice the acronym FRAMED)

Focused – this means that your whole effort is focused on the topic area and the particular aspect of it that you are pursuing. So do not be tempted to add in other things just because they might be useful, interesting, and novel or you just have nothing else to say.

Relevant – any topic area aspect will itself normally represent a large body of knowledge and so one needs to continually ask if a particular element in the knowledge domain is relevant to your particular study.

Authored - any literature review is to be written by its author. This sounds obvious but it is all too easy to fill up a review with cited quotations, paraphrases, summaries and so on so that the 'hand' of the review author is not evident anywhere in the work. When this happens it is not an evaluative review at all but

simple plagiarism. The author's 'hand' must guide and direct the review in an evaluatory fashion so that the review is a message from the review author and not a recitation of what has been found elsewhere. Typically this is done by using one's own skills and knowledge to introduce, comment, add to, modify and extrapolate from various primary sources available.

Measured – this is a matter of selecting and using the focused and relevant materials that you have found. Unfortunately, it is all too easy to pack in information in excruciatingly precise detail and so end up with a laboured entry that treats your readers as if they were completely ignorant of the subject area. So here one needs to just say honestly "is the entry a measured response to my and my readers information needs".

Evaluatory – authors sift through the primary sources looking for materials to use. The essence of this sifting is an evaluatory outlook based on an awareness of your problem theme, your topic area and your own ideas. Care is needed because this process is not about searching for materials that you agree with or like in some way. Instead it is a contextualised response (what do you already know) and that may mean you find materials that are new to you, materials that make you change your own knowledge base and often materials that completely replace what you thought was solid.

Dialogue – a review is a form of argument because good ones are based on a strong theme and in them one is trying to explain to, and convince your readers about something and so it is best if you think of it as a kind of dialogue in which you vicariously challenge them about your review theme and content.

5.3 Integrity and Evidence

This heading sums up research - integrity because it must be your own work and evidence because you MUST be able to show that your results have value. There are basically 4 strands to good work as follows

Dogma – this simply means things you have to take at face value. Most often they are things that are not open to reason in the sense that one is not allowed to question them and in some countries you can find yourself in serious trouble if you do. The problem with dogma is that by definition there is no logical support for it. Just to use a simple example, some faiths require you to have a beard or not eat pork as a matter of dogma – in such cases we usually cannot logically deduce that this is a right or wrong. It may of course be simpler than that since we all invent our own dogmas from time to time – for example it may be very simple such as 'I will never buy a Ford car'.

We all accept dogma but that really is not the issue – the issue is that we should not accept it without some critical thought. There is at least one rational way of exercising critical thought on dogmatic issues and that is asking is the outcome of actions based on it good, bad, neutral or at least does not harm anyone. The trouble however, is that dogma sticks to us like super-glue and we will often go to great lengths to defend it and almost always this is done by sophistry (worthless arguments) and of course the notion of what is good or bad is not easy to define.

Reason – this is the ability to be logical and reason about what it is you are reading or writing. That is you are encouraged to ask questions and seek for a deeper understanding. This may imply that you accept new information, modify what you already know or reject something as no longer valuable.

Honesty – here we are talking about not taking things at face value and being honest with yourself about what you are reading or writing and asking does it all make sense and is it coherent with what I already know.

Motive – this aspect is about your reasons for wanting to read or write something. Now such motives can be high minded or they may be base. One must therefore always guard against tendentiousness (the author simply wants to convince a reader of something and may use any means to do it) in one's own writing and be watchful for it in the writing of others.

5.4 Literature Sources

The available literature is classified broadly speaking into the two kinds described below and ideally we only want to use primary sources.

Primary Sources – that is the first published documents. One can be really pedantic and say the real primary sources are the author's manuscript or autograph but these days we are satisfied with published sources. It will however, often be difficult to establish that something is indeed a primary source.

Secondary Sources – in almost every document you see, there will be elements attributed to other authors – these are then secondary sources.

Be careful not to confuse the above definition with those for primary and secondary data. When we talk of primary sources we are obviously referring to something that is published and exists whereas with primary data it will not exist until a researcher defined, locates and collects it.

5.5 Basic Writing Rules

For Study projects a full literature review will be needed but in Engineering projects the requirements document forms part of the Literature Review. However, even in Engineering it is necessary to write a short review just to form a technical backdrop to your project. It may help you to remember there are two cardinal rules when writing – they are simple:

Respect – always have a deep respect for ones readers and make it easy for them to understand what you are saying.

Need - only quote, paraphrase or summarize when it clearly adds to what one is saying. The key task is to formulate ones own ideas, in your own words but one does this by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

5.6 Literature Assessment

When assessing this element the University will look at how YOU use the sources in what you write and at the range of sources that you use. If either is judged deficient your work may not be accepted as the view taken will be that you are not prepared for work at this level and on this topic. It is expected that all your sources will be mostly primary ones. If there is some reason why this is not possible it must be discussed with the Research Methods tutor or your project supervisor.

5.6.1 Literature Review Ideas

All the following steps are iterative and you must expect to go backwards and forwards many times before you get a review with which you are happy.

Reading/Writing with the Intellect - This is normally thought of as a four stage process that applies equally to what is written (because it is going to be read by someone).

Understanding – this is simply taken to mean that we understand the words used.

Interpretation – are able to find meaning in the words used.

Evaluation – we ask does the meaning have any value – in essence we ask is it true or false.

Contextualization – this implies that everything we read is coloured by what we already know. This idea is taken much further in the idea of hermeneutics (see the notes).

Usage – the literature that you find and evaluate can be used to supplement your own work and demonstrate your mastery of the topic area. This does not mean that you quote, paraphrase or summarise everything you see. As a rule of-thumb: only quote, paraphrase or summarise when it is necessary and it is not common knowledge and it is not an obvious observation.

Argument - Finally, keep in mind that when writing you are dealing with a form or argument where you are trying to persuade your reader about some point or other and that should only be attempted when you are knowledgeable, the argument is essential and you have a deep respect for your readers.

5.6.2 Literature Review Construction

Here is a plan that you can use to construct your own review. It is not infallible and will require conscious effort from you and it must be based on a thorough evaluation of the literature.

Step 1. Purpose - the purpose is to fully prepare your mind with all that you need to know about the topic area and the particular element of it that you are focusing on. The idea is that what you write shows your mastery of the topic and in fact you have become an authority on the topic area. So a review is not a long list of quotes, paraphrases and summaries, it is an evaluatory discourse. That is, readers will want to know what YOU have to say based around what you have uncovered in the literature - so readers must see what you have found and see what you have to say about it.

Step 2. Topic and Aspect - Make sure you are clear about your topic area and which particular aspect of it you need to explore and understand in order to be able to effectively carry out your planned research.

Step 3. Select a Theme - Use your project problem definition, target and outcome to guide you in selecting a theme that will connect all the various elements of your review together making it a lucid and progressive discourse. (Don't be afraid to alter the theme as you go along if that becomes necessary)

Step 4. Your own Views - Try to make a list of your own views, ideas and knowledge. Remember, the review is an evaluation of what you find not a recitation of it. If all you do is tell us what you have found you may not even pass because almost anyone can write a review on any subject if all that is required is to more or less recite what has been found. So you must structure the review around your theme and your own ideas and thoughts.

Step 5. Make a Review Content list - Based around your theme make a list of all the various topic strands that you need to know about. It may help you to think about strands such as: organisational, administrative, functional, social, technological, cultural, ethical and so on or some other structure best suited to your topic – but it must be progressive and logically take you through the topic area. This is not about writing down everything you know it's about giving your readers a focused discourse on your chosen topic area. Commonly it is found that it is useful to start as follows.

5a. Basic definitions and terms that need to be clear for the core topic area. (Be careful to note any abbreviations)

5b. Map out several important areas or problem space dimensions. Now it is impossible to be general here so for example if I were looking at mobile devices and their use in business I might map out the following elements: value, attitude, use, limitations, practice cost, ease of use, learning curve, effectiveness and so on. Please be careful here to look for significant things not just drag in anything and everything. Once you have made this list you may add to it, modify it or discard from it as you go along.

5c. Work out how you want to end the review - often this just sums up your point of view but you may have other ideas

5d. You may like to include some statistics if that is relevant. But don't let this run away with you and so the review just becomes some sort of justification based on statistics. Remember, statistics almost never tell us anything about the topic itself and only tell us things related to the relative importance of certain things we have identified.

Step 6. Literature Searching - Armed with your theme and list of elements start your search for suitable material but be very careful to record the exact details of where everything may be found and checked. The search may start with the Internet or a special tool like Google Scholar but must move on to respected publications.

Step 7. Structure - The final step is to structure your themed list of topics using headings, subheading, paragraphs, bullets, tables, diagrams and so on in order that we get a coherent and lucid discourse on your chosen subject area. This is not a trivial matter and you must expect to go over it many, many times before it is really an example of your very best work.

5.6.3 Reference and Bibliography

References are to primary sources that you use in the text of your written work. A bibliography is a list of sources you have identified as useful (including references) but not necessarily used. The University will look very carefully at any references to see if you are prepared for study at Master's level in your chosen topic area. Overall, the expectation is that you will list at least 10 sources. For each source you must consider its:

Currency – looks at publication date and be aware of changes in technology. In technology books are soon dated.

Completeness – Make sure you are looking at the final version not some draft or abstract.

Uniqueness – is the source a primary one

Coverage – Use your list of sub-topics to ensure that you cover all the areas required so that you are fully prepared. But make sure that you are not including multiple texts with essentially the same content.

Range – Make sure you have a good range of authors.

Authority – ask is the text authoritative. This can be done by considering the author, publisher, writing style and currency. It is also possible to use citation indexes to see how often the source has been used.

Accuracy – Is the information correct? If you cannot be sure then you must not use it.

Relevance – Make sure that your sources are relevant to your project topic.

Usage - The basic usage strategy is:

Find – Relevant texts using a library index, the internet, online book stores and so on.

Evaluate – Once you find a possible source you must evaluate it for content and relevance.

Contextualise – that is fit this new source into your personal knowledge base.

Cite – If you use a source it must be listed in your reference section and cited in the text correctly.

Discuss – You may include something from a source in your work as a copy (quote), paraphrase or summary but in all cases you must introduce it, comment on it at cite its source.

5.6.4 Evaluating Internet Resources

When using internet resources it pays to be careful and always sceptical because of the following factors:

Anarchy - anyone can publish just about anything on the Internet

Validation - authors do not always have their materials checked by an authoritative third party

Tendentious – when the author wants to convince you of something and will use any means to do it.

Honesty - authors may not always be what they seem and may assume personas, lie or make false claims

Consider – the motives of those who publishing on the Internet

Trust - in research trust nothing until you have good cause to do so. This is the opposite of what we do in our daily lives in that we tend to trust until we have reason not to.

Context – be aware of the context of what you find. For example is it a University site, is it a manufacturer and so on.

Accuracy – this simply means is the information correct. You need to be aware that information might be validly collected but still be quite inaccurate.

Validity – this means that we ask is this a valid source in the sense that it was constructed in a reliable manner. Any lack of information on proof readers, editors and publishers means that mistakes are more prevalent than in print and therefore increased scope for innocent error and for outright deception.

Authority – this means was the author competent to create this material. For example any one could have an interest in say Emotional Intelligence and quite easily create an internet article on that subject but it would not have the same authority as that of a University professor who has spent years researching the topic.

Uniqueness – here we are asking is this an original work (a primary source)

Completeness – this may simply be described as asking if the work is the final and finished version. You need to be very careful here else you might find yourself using the material from the earlier part of the work which in fact was augmented at a later stage.

Coverage – this means what is the scope of the source. Now this does not mean that a source will cover everything on a given topic but it should be clear as to what it is covering.

5.7 Citation Examples

The following set of examples is intended to show some often poor use of citations and also some sound ones. These examples should be studied with care so that the flaws they illustrate may be avoided. The quotes are from a range of sources and topics and in your study of them you need to concentrate on the form. Now assume all the following were all written by the Research Methods tutor so the comments will be offered in the first person as if he is talking to you

These are just simple examples and they do not imply you must use italic or indenting as that is only used here to show clearly the pieces of work being looked at.

Example 1.

Lyau & Pucel (1995) found a link between training and productivity for their sample of Taiwanese car part manufacturers. Bartel (1994) found that training is a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors. Bishop (1994) and Barron, Black & Lowenstein (1989) both found that training increases management estimates of productivity.

This is poor because I only told you what the cited authors said. I did not introduce the author's words, nor discuss them and it's almost impossible for you to see what point I am making other than the obvious one that productivity and training may be linked – in effect it is not my work at all and there certainly is no sense of evaluation here. We might have written

Many authors (Lyau & Pucel 1995, Bartel, 1994, Barron, Black and Lowenstein 1989) found a link between training and productivity and that training is often a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors ... followed by your comments/discussion/analysis etc

Example 2

It has been found that because Arabic words were written by copyists who did not use vowels that over time the meaning of some words has been lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. One way to deal with this is to use assonance and in this paper that approach will be taken (Noldeke 2003, p45).

The problem is that it looks as if I attributed the entire paragraph to Noldeke. So you can have no idea which part of the paragraph was my own thought or maybe none of it was. This is bad practice and some tutors even regard it as blatant plagiarism. The fact is that tutors when they see this form in will automatically assume that all the student has done is paraphrase what he has found and none of it in effect is representative of any student thought and will mark the work down because of it. It could have been written as follows:

There has been a long standing problems with some early Arabic manuscripts in that many words have become obscure and even in context they are still unclear. Bigly and Ahmed (1978, p340) and others have shown conclusively that because Arabic words were often written by copyists who did not use vowel, over time the meaning of some words became lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. It has been usefully suggested by Noldeke (2003,p87) that one way to deal with this is to use "assonance analysis" to study word endings and in this paper that approach will be taken and in particular we will look at some early Arabic poems by Averroes.

You can use the bracketed form if you just want what amounts to passing reference to a source as in the following example.

In two recent works (Harding 1986a, p.80; 1986b, p.138) it has been suggested that ...

Example 3

St. Clair-Tisdall (1994, p45) said in his seminal paper on Organisation Synergy that "change in organisations is an inevitable consequence of growth" – this is an interesting observation and implies continuous IT progression and updating. Knowing this we can support Briggs (1999, p23) who said that OO is now routinely used in the computing industry.

This is poor because the first statement by St. Clair-Tisdal is clearly obvious and that by Briggs is common knowledge. Also it is not entirely clear that the second sentence leads logically from the first one. The point is that using citations here was unnecessary and therefore worthless. *We might have written.*

It is obvious change in organisations is an inevitable consequence of growth and in the modern world that must imply continuous IT progression and updating. Many authors, notably St Clair-Tisdall and Briggs have commented on how these naturally progressive elements may be factored usefully into a company overseas sales policy and....followed by your comments/discussion/analysis etc

Example 4

Suppose, in your reading you come across the following in a book by Noldeke. But the bit that interests you is by Frederickson – how will you set about properly using and referencing the Fredricksons quote?

Tools are needed if we are to measure software quality in a meaningful way. The idea of quality, as we know, is intangible since many views are possible. It follows that we must define some terms in order to measure quality. It is useful to note what Fredrickson said: "Definitions of what quantities we need to measure in order to assess software quality are at present arbitrary since as far as we know they have no connection with functionality".

This does not mean that they lack a rationale, but simply that professionals disagree on the definitions themselves and so it follows that

In this case the correct way is to find the Frederickson book and use that because it is the primary source. Quoting from secondary sources will only be tolerated in proven cases where the primary source cannot be found or for other reasons is inaccessible and it must be done in the correct manner as shown in Workbook 8 for secondary sources.

Example 5

Can you work out what the following extract from a piece of student work is saying?

It is argued that tacitness, complexity, and specificity in a company's skills and resources can generate causal ambiguity in competency-based advantage, and thus raise barriers to imitation (Fahey, 1989). This is to rise a company's distinctive strategic positioning so as to possess some form of sustainable competitive advantage.

The sentences is obviously copied as it is very, very unlikely that any student would write with such academic complexity and obscurity – lines like this are not designed to communicate they are designed to impress the reader not further his understanding. What it in fact it is saying is that some skills are very difficult to duplicate and this may mean that growth may be restricted. We might have written.

Fahey in his 1989 monograph has stated what should be obvious but he nevertheless less shows conclusively that companies often do not realize that some skills are very difficult to duplicate and this may mean that growth may be restricted or if you like it's not all that easy to copy a skill. ... followed by your comments/discussion/analysis etc

5.8 Literature Reviewing Cautions

Writing a literature review is a difficult and time consuming task if it is to be done well and there are no short cuts to sound scholarly work so here are some final pointers.

Justification - A literature review is NOT a justification for your research idea and such a review will never be regarded as explaining to the reader the topic area and your evaluation of it. Justifications often take the form of filling up the review with statistics but such an approach carries no real value in convincing the reader that you are master of that topic area.

Structure - It is very common to see students write down things in a literature review as they occur to them. This practice might be fine for notes but it is obvious that the way thoughts pop into ones mind or information is discovered is often anything but logical or structured. To communicate in writing effectively you must impose some structure on what you write else readers will not be able to see any progression in your thought or in the topic.

Pretence - some students try to be scholarly and pack their work with quotations and paraphrases – this then become not an evaluative review of what was found but a recitation of it instead. It is correct and desirable to tell your readers what you have uncovered but unless you make comments and add your own views on what is found the work will be regarded as a worthless recitation.

Non Review - some students just write down what they know without any references to the literature – this will always lose you marks as no one will believe that you obtained that information by your own brainpower without any outside assistance.

Experience – students often claim that what they write is all down to experiences but again no one will accept that. The way you use experience is in your evaluation of the sources, comments on them and building up your own arguments.

Inclusion – Preparation of the mind for your topic area does not mean you write down everything you know that might be relevant. What it does mean is being focused on your topic area and becoming expert in that. For example, an Engineering project where the literature review contains page after page devoted to telling the reader about every conceivable life cycle is hopeless and in such cases there is almost no thought over what is written and so it is worthless. Similarly, if a study project was looking at eCommerce as a way of selling drugs then page after page telling us about various drugs, treatments and prescribing practices is worthless in the context of just selling drugs. It's not volume is wanted but considered content.

Common Knowledge and Obvious - Quoting or paraphrasing material that is either obvious or common knowledge implies that you have not looked at the sources beyond the first page or forward. Here is an example from a project document. "Poston (2000) stated that organisation expected ERP systems to deliver improved performance". This is worthless as it is obvious that they would want this and to say it makes no valuable point at all - its no good trying to say things like this as if Poston was enunciating some law of the Universe or a point of huge importance on some new and valuable angle related to ERP - no he is just stating the obvious.

Bad Citations Style - It is very common to see the citation form (Briggs, 2000) placed at the end of a sentence or paragraph. This can ONLY mean that all you have done is paraphrased, summarised or copied that section. This practice is more or less plagiarism and is representative of a very lazy attitude that assumes that just expressing something in your own words is a valuable contribution - its is not because YOU are saying nothing and what you are supplying is not really your own work at all.

Activity Definition - Some students use the Literature Review to tell us what they are going to do in the research. This will result in a zero mark as what is to be done is covered in the Research Design so repeating it here is valueless. This practice is a certain sign of laziness.

6. WORKBOOK 6 – MAJOR PROJECT ELEMENTS

This workbook is intended to help students formulate clear project elements but here that what is said here is a mechanical process and it is your responsibility to make sure that what is written down makes sense.

6.1 Scope and Scale

Scope and scale are meant to be considered carefully otherwise a project which is out of control and way beyond your capabilities in the time available may occur. Alternatively, the scope and scale may be set so that the problem becomes trivial and the idea is rejected. So please take note of what these terms mean as far as this course is concerned.

Scope – this means something like selection or choice. So for example, if I were looking at training in desk-top packages I might select just Excel or I might select Excel and Access and so on to focus on. The point is I set my scope by being selective.

Scale – the means something like number or extent. So for example if I set my scope as looking at Excel I now need to set the number of users I will include in my study.

Scope and scale are two dimensions that set a frame around your work to bring it into sharp focus and exclude everything else. You need to put limits on both these dimensions but it is most important is to be clear about scope – that is, what exactly to include in your study, normally, just include ONE significant thing.

6.2 Presenting Problem

In any project it is usual to choose an area of knowledge and practice to be its topical focus. For example, one might choose modern usability issues, automated network management, digital paper and so on. Once one has a topic area it is necessary to choose one problem theme within it to be a sharp focus for a primary data research effort whose aim is problem resolution or partial resolution leading to a strategic business IT significant benefit. In general, it is not all that easy to give a simple and all embracing definition of the notion of problem but the following has proved to be useful.

A problem or issue is something that is a matter of concern or debate within the topic area and whose resolution might bring benefits. (Checkland 2003)

In practice this means a problem is an object not an activity. For example, stating the problem as “how to ride a bicycle” is incorrect since this is a question about the problem - the problem is “riding a bicycle”.

Another difficulty is that students often write down the problem in such a way that it is an answer or solution to the problem. So for example, if one writes a problem statement as “lack of training” then implicitly that is a solution as well. When this happens it is almost certain that the writer is not thinking about the problem at all but is obsessed with a particular solution. In this particular case the real problem might have been “errors in data entry” and one of many possible solutions is training.

6.2.1 Problems are Rarely Simple

It is easy to become blasé about defining a problem and this is often compounded by our desire to get to a solution as quick as possible – therefore I urge you to take care and thoroughly analyse the problem. There are perhaps three elements that need to be understood.

Reduction – it is desirable to simplify problems but that may also mean that you oversimplify and so one ends up with a very inadequate problem definition or model and of course if you do that your solution may fail in part or even totally.

Context – every problem exists in a context of some kind and we often call it “the problem situation” and if you are to have any chance of an adequate understanding and definition of the problem you must appreciate the context in which it exists. To give a simple example, on this course writing an adequate Research Question is problematic for students because the ideas will be new, they are working full time, they have family commitments and so on – these things affect your ability to get this work done. But for me writing a Research Question is relatively easy, because my context is different: I have experience in this area, I am retired so no work pressures to contend with, I don't have to worry about failing and so on.

Perspective – everyone has a different perspective on any given problem. For example at work you may see a particular problem one way but your manager may see it in quite a different light. Now, we cannot help taking a perspective but we can be aware of it and try to moderate its affect on the way we define the problem.

6.2.2 Defining the Problem

It is a good idea to construct one's own definition of the problem and to do it in as few words as possible. Notice, that it is your own definition not one you might look up in a book or on the internet (though you might start with that) because there is often little learning value in just copying a definition as far as deepening your own understanding is concerned.

Remember, that any definition one constructs will not be absolute and accepted by everyone - but in research this is not a problem as long as the researcher makes it clear what particular definition is being taken. Do not take this process too far and end up with either over-complicated or trivial definitions - they must be thoughtful and comprehensive. So it is recommended you start by thinking about six things where the acronym CCC-APE (stated as "triple C APE") is used:

- Characteristics** – observable features or facets of the problem idea,
- Context** – every problem exists in a context of some kind and it must be understood
- Causes** – every problem will arise due to some causes or causes
- Associations** – every problem will have links to other situation elements,
- Perspective** – when a problem is encountered it will always be from a certain perspective
- Effects** – say what effects ensue in the real world if the problem is not resolved.

6.2.3 Defining the Problem - Example

Let us suppose that a student has identified the problem theme as Phishing. Naturally, the student will be concerned that this is a good idea and would like confirmation of that before expending time on it. One can ask the course tutor, but he/she is not expert in everything so at best one would only get an opinion as a response so how should a researcher proceed. So for Phishing a researcher might note the following:

Characteristics: illegal, intrusive, upsetting, preys on those who trust their fellow man, etc

Context – phishing may occur at home or at work and in both these situations one naturally feels comfortable and secure and our systems may be well protected. However, that context can lull one into trusting the messages we get and it is exactly that element that the fraudsters want to exploit

Cause – it seems the cause is to do with greed or wanting to harm someone and feel, rather sickeningly, pleased in being successful at it. Notice an interesting thing here – mostly knowing the cause helps you to solve the problem but here most would say it's insoluble but possibly preventable.

Associations: email, chat, file sharing, etc.

Perspective: management (but try to look at it from several perspectives as well)

Effects: destroys confidences in the system, may lead to personal or company losses etc

Normally, it takes quite a few attempts before a definition that is lucid and comprehensive is obtained. Remember, the definition must also be useful within your research study – that is, it's no good having a well formed definition that does not offer a sound basis for a research effort.

Now here is a first attempt

In the modern world email is a technology that almost everyone uses whether in the home, at work, on the move and indeed it seems to follow one around. Typically, email is a simple one-to-one message passing technology but it is now offered with enhancements that include voice, video, chat, file passing, file sharing where suppliers are attempting to present a complete communication environments. With such a technology come problems and one such problem is identity theft and one way of getting this is known as Phishing. In its simple form an unknown, but apparently authentic, source asks for personal details and then uses them for fraudulent purposes. The problem is identity theft using email systems where a message poses as a legitimate requestor in order to fool the recipient into thinking it is legitimate request. The problem in computer system is known as Phishing.

Here is a final attempt (but most often there are several intermediate attempts)

Phishing is identity theft using email where a personal message seeks confidential or private information from its recipient whilst posing as legitimate request. The intention therefore is to fool the recipient into trusting the message and releasing information which can subsequently be used for fraudulent or other harmful purposes.

6.2.4 Cautions on Problem Definition

The acronym CCC-APE is just an aid to formulating a definition so one should not worry whether something is a characteristic or an effect - that does not matter very much because the whole idea is to uncover problem aspects and expand one's understanding of the problem theme.

As a very rough guide one often finds that the final definition must come down to about a third of what we start with. In most cases if one is familiar with the subject it is possible to create a good definition in about 1 to 2 hours and then if necessary update it as your project progresses as it is almost certain that there are elements that have been missed or imperfectly understood.

6.2.5 Problem Size

It is hard to measure the "size" of a problem because there is no scale on which to gauge it. But one can look at three aspects to get some idea.

Observable Effects – think about the effects of the existing problem and try to assess their seriousness in terms of the context in which it is set. In simple terms just ask "is it worth solving".

Causes – as was stated above, mostly knowing the cause helps you to solve the problem but some problems are so complex or so embedded in human nature that solution is impossible so in those cases we go for prevention.

Form of Answer – perhaps a better guide is to think about the form of answer and see how extensive, important and how hard it is to get. For example: one student wanted to deal with password overload – a clear problem with which we are all familiar but his outcome was a set of guidelines on how to construct good passwords but in my view that was a trivial answer to the problem because those guidelines can be found almost anywhere and it is doubtful if that goes anyway to solving the overload problem.

6.3 Project Target

When you think of a problem you normally do it in relation to its effects. It follows that you have to think very early in a project about what effects will be generated if you can resolve the problem – these real world effects are called the project target. Normally one settles on one major target although it is permissible to list more than one. Targets are effects so these are typically introduced by a verb form (increase, reduce, remove, reduce etc) and tend to be such things as: improved accuracy in data entry, to gain infrastructure resilience, streamlined workflow and so on.

6.4 Project Outcome

It is obvious that at the start of a project we do not have its outcome – but we can have some idea what its form may be. Therefore if we know our target we can speculate about what project outcome credibly might generate or go some way to generating the desirable target effects if used by situation actors. Outcomes are objects and so are typically expressed as nouns: Here are some examples:

The target of "improved accuracy in data entry" might be generated by a project outcome of a training needs assessment report or a training plan for use by departmental managers.

The target is "to gain infrastructure resilience" might be generated by a project outcome of a revised backbone design or a set of recommendations for new technology for use by the IT development team.

6.5 Situation Actors

Whenever you state an outcome you must always say who will use it (called the situation actors), how they will use it and hence show how the target effects are achieved. If you do not do this with care one often ends up with a worthless outcome because it is unusable or unsuitable.

6.6 Speculation

It is often useful when thinking about the solution to a problem theme to think of it as based around or generated by some personal theory a person holds about that problem and its setting. Essentially, one gets at this theory by speculating about causes and possible solutions routes. It is not easy to say how to speculate but it can be said that it is aided by a thorough literature review, personal experience and a deep consideration of the problem theme perceived in a given situation.

For example suppose the situation was related to issues with application software implementations in business not being as successful as expected. Recognition of this problem theme is a first step but if one is to do something about it, it might be useful to thoughtfully speculate on why success is lacking in this area. It follows that one might speculate that this lack of implementation success is due to poor implementation

strategies, or poor user training, or poor project management or any number of things. Notice that there will always be rival speculative ideas and that is why one must be thorough in looking at the literature and using your basic knowledge and experience to open up the problem situation in order to at least have a credible theory as to the most probable solution route otherwise one might just waste time on chasing nothing of value.

Do not let this idea run away – this is not about natural laws of the universe such as Ohms law or Archimedes Principle – here one tries to establish a personal belief about a situation and its problem theme. So after speculation one might express ones personal theory about the above example as follows.

It is believed that implementation of application software is proving difficult and this may be due to poor implementation strategies. It follows that if this is the case and better strategies can be defined then implementations may prove more useful in the future.

Notice that my theory points to a particular form of answer to this problem theme and in this case it is related to perhaps a document that explains how to formulate implementation strategies based on a consideration of user needs, application intention and business objectives. Occasionally, the theory may be embodied in a scientifically constructed hypothesis but more often than not in technological research it is expressed informally as an idea.

6.7 Primary Data

Primary Data is data is new data in the sense that it will not exist as a set until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data set is representative of some aspect of the area under investigation and can be processed to get a defined outcome that will resolve or partially resolve a stated problem theme when used by situation actors. All projects must be based on the collection and processing of primary data.

6.7.1 Primary Data Collection Protocol

Within every project there has to be a collection protocol for the practical collection of the primary data. Every complete protocol will have 5 features:

Vehicle – this is the primary mechanism or technique employed by the researcher, typical examples are: interview, questionnaire, observation, role playing, seminar, focus groups, document searching and so on

Recording Profile – this describes how the data will be physically recorded. Typically we might use: written report/transcripts, formatted record sheets, video, sound recording, computer logging, excerpts from documents and so on.

Sample criteria – this is a profile that allows the researcher to know that he/she has a valid sample point from which data is to be collected. For example, if we wanted data on business uses of Digital Paper we need a profile of who we should ask for that information. If we do not have a profile we may not have any consistency in our data and it may therefore be meaningless.

Permission – you have to feel certain that the information you seek is legitimately available to you.

Ethical Profile – you need to be clear as to what you are doing, the way you are doing it and what you are asking for is ethically acceptable. Two things are at stake: the results may be biased and the results may not be acceptable in the sense that they cannot be ethically used.

6.7.2 Project Purpose in a Nutshell

Students sometimes get confused over what a Master's project is about. Consider a topic area like Digital Paper which is likely to be a very hot technology in 2008. A Master's project is not about producing a long narrative on Digital Paper explaining what it is, how it is used and what the technological infrastructure to support it might be. A Master's project is about identifying a problem theme in Digital Paper and then collecting and processing primary data into a form that helps you resolve that problem theme based on ones own personal theory. With this in mind, consider the following examples.

Example 1. Suppose I want to define all the various accounting functions so I pick up a manual for my in-house accounting system and then go through it looking for all the various accounting functions and listing them – is that primary data and is this a valid research purpose? No because in the first place one might just regard the manual as listing the functions anyway so in effect the data already exists, secondly, this is just one book and so its content might be complex, trivial or totally unrepresentative.

Example 2. So if I extract (my basic activity) instances of phishing (my problem theme) from an email log that would be primary data because even though the email log (secondary data) obviously exists, the list of phishing instances (my primary data) as a set did not. My purpose being to process this collection of primary data to find out the most common sources of phishing and express my findings in an evaluatory report (my form of answer) to be used by my managers to eliminate or reduce successful phishing cases.

Example 3. If I conduct interviews in order to describe (my basic activity) a user purpose regarding illegal downloads (my problem theme) in my company with selected employees the interview transcripts are my raw primary data because the transcripts did not exist before the interviews took place. My purpose being to process this collection of primary data in order to develop a policy (my form of answer) to control illegal downloading activity for use by IT personnel in monitoring internet activity.

Example 4. If I look through written reports (secondary data) on security violations (my problem theme) for a particular company with a view to identifying (my basic activity) the root cause of each violation then even though the violation reports exist the list of root causes (my primary data) did not so it is primary data. My purpose being to process that collection of primary data to create a strategy (my form of answer) that will alleviate or remove certain kinds of violation in future when used by security managers.

Example 5. If I plan to build an application for processing student MSc marks (my problem theme) then I need to ascertain (my basic activity) the system requirements (my primary data). My purpose being to process this collection of primary data to create a design (my form of answer) for the marks processing system which can then be used by software developers to produce a working application.

6.7.3 Pre-processing Primary Raw Data

In many cases it will be necessary to process the raw data that one collects into a structured form of some kind so that is easier to use when generating the final project outcome. For example, if we have a series of interview transcripts it is obvious, that in that form, they are not easy to use so we might perform a pre-processing phase to get the core data into a more structured form that then constitutes our primary data set before the main processing phase that generates my project outcome is carried out. For example, suppose I examine company documents on misuse of IT system resources by employees. In this case I might proceed in two ways to get my structured primary data collection.

In line processing – that is I define my structure before I start and then as I come across a misuse example I structure it there and then. However, the disadvantage here is that you have to continually look back to see that you are not recoding the same data again and again from other incidents and so it tends to disrupt the collection process and make it longer to complete.

Pre-processing – here I wait until I have been through all the documents and then I use my set of notes to systematically work through the whole raw collection and form my structured collection that way.

6.8 Writing a Research Question (Study Projects)

This is intended to encapsulate your whole project idea and intention into one lucid question. Ideally one wants open questions that request information in the form of an answer. Questions can sometimes be like commands used to elicit a response and others such as "Would you pass the salt?" looks like a question but in fact is a request or action, not for an answer. In Research Methods, however we will only look for questions that elicit information.

The simplest questions implicitly or explicitly request information from a range (finite or infinite) of alternatives and these are often called bi-polar questions but more generally question ask for information that includes explanations, description and definitions. An interrogative word is a word used to start a question. All questions have a natural structure to them and that structure can change dramatically when you change the interrogative. In English the following is a list of interrogative words although some of them are rather old fashioned now.

Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, is/are, and can.

6.8.1 Questions that are not Questions

It is often difficult to write something that in English could be taken as a question. Now I am sure that in daily life everyone knows how to ask a question but when you write something down you are entering another world. Consider the following two lines – would they be understood as proper questions?

How to sharpen a pencil? Or What a pencil can do for you as a student?

Now these clearly ask for information but if you spoke these fragments to someone they would not quite see it as a proper question – in English such fragments would be understood as a kind of heading to a list of instructions for sharpening a pencil or a list of the benefits of using a pencil. That is that they imply that someone is giving you an answer not a question.

6.8.2 Basic Research Question Forms

It is best when attempting to construct a question to think about what sort of answer to expect – now in normal everyday life we do this instinctively. For example, you would not say “is this the right way to Pablo’s restaurant” if you wanted actual directions because that question form could only give you a Y/N answer. Instead you would probably say something like “how do I get to Pablo’s restaurant from here” and reasonably then you would expect an explanation. Broadly speaking there are four sorts of answer:

Bi-polar answers - Essentially questions that imply a limited range of possible answers. Typically, a bi-polar question starts with a word such as WHAT, IS, CAN or DOES.

- Is it possible to sharpen this pencil? (Y/N)
- Does it make sense to allow children to sharpen pencils (Y/N)
- Can a blue pencil be sharpened easily (Y/N)
- What is the common view of staff about using blue pencils? (Disagree, agree, etc)

Bi-polar questions can of course be useful but more often that not they have no great utility with forms such as “Can a green pencil be used in place of a red one?” Well of course it “can” be used so the answer is bound to be YES and so the question is pointless.

Explanatory answers – where the expected answer is an explanation and it is often in the form of a procedure or process. Typically, explanatory questions start with ‘HOW’ or ‘WHY’. For example, “How can a pencil be sharpened safely by young children?”

Descriptive answers – where the expected form of answer is a description most often in the form of an evaluation. Typically, these questions start with WHAT or WHY. For example, “What is the purpose of HB0 pencils?” (a simple explanation) or “Why are HB0 pencils difficult to sharpen?” (an evaluation)

Exploratory answers – where the expected form of answer implies an exploration of something. Typically, exploratory questions start with HOW or WHY. For example, “How should we use HB1 pencils best in drawing figures?” (often an exploration leads to an explanation)

The most common interrogative words to start questions are: what, where, would, in what way, can, is it, why, which, where, how, does, who, why and do – whatever word you use, always ask what form of answer is implied by each of them. You must be sure that whatever form you decide on as answer that you can actually construct it and when it is constructed as part of your research it is in fact useful strategically in some way.

For example, suppose I decide that the form of answer I want is “The role of technological innovation is business success”. The task you now have is to ask yourself whether you know how to express a role (write it down if you like) and whether knowing about this role will be of any use.

6.8.3 Research Question – Why are we asking it?

In normal everyday life questions come at us more or less all the time. Sometime we just answer them but more often that not we have a tendency to ask “why do you want to know”? It is therefore always useful when setting out your research question to ask why you asking it. That is you say to yourself, if I have the answer to this question then there will be some good outcome because of it. Sometimes we embed in our questions why we are asking them but mostly we do not. You will see later however, that you will have to make the reason plain in the aim so one might as well think it through at the question stage as well.

6.8.4 Research Question Form of Answer

For any Research Question there will always be several possible forms of answer arising out of ones personal theory about a problem situation encapsulated in the question. Ideally one would like the research question to be worded so that ONLY one form answer is possible and that is the one our theory suggested but often that is not easy to do so one normally has a range of options and competing theories to choose from so one looks for a form that interests you or looks to have the most utility. Do not be tempted to have multiple questions all in one sentence or look for multiple answers since it is better to focus on one significant output form. Table 4 lists the main forms of answer to help you when considering your personal theory.

Category	Typical Interrogatives	Expected Forms
Bi-polar	does, is, are, what, when or can	A list of possibilities
Explanations	how, why, who or where	A report, a model, an equation, a theory, a design, an evaluation etc
Explorations	How, who or what	A list, explanation, a comparison matrix, a pattern, a survey report, a theory etc
Descriptions	What, who or why	A report, a process or procedure, a model, a policy, a strategy, a theory etc
Table 3. Research Question Outcome Possibilities		

6.8.5 Strategy for formulating a Research Question

There is no easy way to do this and no real templates for it either so a good formulation will require some clear thinking and effort and that will show the examiners whether you are at Master's level or not in your thinking skills. A typical structure that you might use can be remembered by using the acronym IO-APTS. Therefore the IO-APTS elements are:

Interrogative – what is your key interrogative word (how, why, what etc). You should note that some interrogatives need to use two words if a proper question is to be formed. For example, “how” on its own will not normally make a question but when you say “how can” it is clearly a question.

Outcome – here one asks what sort of answer and what form it might take. Answers might be yes/no, an explanation, an exploration, a description which may be expressed at the end of the project as a report, a model, a list and so on.

Actor – the person or persons who take the outcome and use it to get the target effects

Problem – focusing on a single significant problem and be as concise as you can.

Target – what effects will be observable and measurable in the real world if you can resolve the problem. Effects are things such as efficiency gains, provide or enable better communication, increased accuracy and so on.

Spotlight – put the spotlight on where the primary data or information needed to answer the question might help come from.

Generally, the Research Question should ask always about the outcome and who will use it to solve the problem to get the target effects. However, the order in which the question features go in the sentence is largely governed by the interrogative used. It follows that it is possible to write the question in several ways depending on the interrogative used. The interrogative “what” is often used and then a good question seems to use the features in the order: Interrogative, outcome, actors, problem, target and spotlight. Here is a student work example:

What (**interrogative**) portfolio of accounting best practices (**outcome**) can be identified for use by junior personnel (**actors**) to avoid billing delays (**problem**) in order to improve the quality of response to customers (**target**) based on an examination of the initial accounting processes stages (**spotlight**)?

I used “what” here because I am looking for a process and this interrogative seem very appropriate for that kind of outcome form. Depending in what we want we might end up with a different interrogative and a different question format. Suppose we did not want to find the best practices but just explain why the current ones do not work then we might write the following but as you can see we get a slightly awkward sort of construction when we try to add the outcome and the actors.

Why (**interrogative**) is the current portfolio of accounting best practices (**spotlight**) as used by junior personnel creating long billing delays and poor quality customer response, (**problem**) expressed as an evaluation report (**outcome**) for use by application consultants (**actors**) to ensure there is an informed (**target**) management personnel on possible process changes.

Whatever interrogative you use you must always fit in the 6 features to make it comprehensive and this will often require a little ingenuity. One very common error that you must guard against is asking how the outcome can be used because in most cases it is obvious. To use a trivial example, one often sees questions that say things like “How can I use my training as a driver to drive a car?”

6.8.6 Meaning in a Research Question

This section has looked at the structure of a typical Research Question but it MUST be thought out step by step and even then one has to think does it make any sense, is it a focused question, what sort of answer should I expect and so on – there is simply no substitute for careful thinking.

Once you have formulated your research question and have a good idea what form the answer will take then its time to test it using the following ideas. Now be aware that this is just a test of structure and of itself it does not mean the question makes sense – there is no way to do that other than using your own brainpower and common sense – if it makes sense to you it will probably make sense to whoever else looks at it.

English – does it read correctly in English as a question?

Paraphrase – if it's a good question you may be able to ask it in several different ways – so try to do that until you get a formulation, perhaps with a different interrogative, until you are happy with.

Bi-polar – this means that the question has a fixed and limited range of answers such as “Y/N”, “bad”, “good”, and “excellent”. This type of question can of course be useful but the problem with them is that such answers do not have much utility – that is they do not tell you anything of value in terms of what action or actions you might take. You are advised to avoid such questions for your project.

Discussion – look at your question and honestly ask ‘will this question produce discussion?’ – what this means is to ask ‘who am I writing this question for and would it interest them’. Try not to think that you are doing this for your Research Methods tutor but try to think what you would do if you were trying to get funding for research to get an answer to the question from someone.

Answer Form – try to work out what form or forms the answer will take (typically: bi-polar, explanation, description or an exploration) – if you try to avoid this aspect you may find yourself in serious trouble with your research.

6.8.7 Common Errors in Research Questions

The following are typical errors found in student written Research Questions – they can all be avoided if one takes just a minute to think through what has been asked and what sort of answer is likely.

Not a Question - to an English speaker the following would not sound like a question, instead it would sound like a heading to a list of instructions or a procedure. "How to make business application development productive at XYZ Corporation?"

Multiple Questions – It is never a good idea to try to put TWO (or more) questions into one as in the following example - one is about testing and one is about bugs they are quite different things. "How can software bugs be minimised and the testing cycle shortened in the development process of an Inventory System?"

Obvious Answer – these are cases when no research is needed because the answer is either obvious or common knowledge. Questions like this show a serious lack of thought – take the second example below and it is easy to see that the answer to the question is bound to be YES - of course a productive work-life balance "CAN" (but might not) be obtained so there is nothing of any value whatsoever in a question like this. Similarly, it is easy to explain how a better development process can increase productivity.

"How can a better business application development process increase the productivity at XYZ?" or

"Can a productive work-life balance be achieved with telecommuting for technical personnel?"

No clarity about each IO-APTS feature - I would recommend that you add in brackets the 6 feature names as I have done above when you write your question.

Each IO-APTS feature occurs once - this is important because it's again all about being clear what each feature is and helping the reader understand what it is you have written.

IO-APTS features in some cases may be combined - you may do this if the question sounds more natural to you but be careful that you really do know what each feature is.

Confusion with target and problem - this is often caused because a student gets muddled up about the effects wanted and what the actual problem is. Again when we see this it makes us wonder if you have understood the very basis of your own project idea.

Confusion over target and outcome – this is perhaps the most serious error and it would imply that you do not understand the most basic distinction.

Please remember that it is possible to write a very poor question that exhibits more than just one error type and yet has all the required features - there is simply no substitute for thinking about what it is you have written.

6.9 Primary Data Generation with Activity and Spotlight

Based on a problem theme, theory and the form of the project outcome expected one needs to formulate a process to create a structured collection of primary data. There is no algorithm for doing this and one has to go carefully through the steps: define the data, locate the data and decide on a protocol to collect that data reliably.

Activity – this is also known as a Basic Activity for Generating Data (BAGeD). All it means is that one has to do something (an activity) to get the data and these activities must inform you how to write down the data. Possible activities might be: account for, collate, assess, profile, illustrate and so on. Notice that activities like “interview” are of no value here because they don’t tell us what to do with the data. That is we can say “profile the inventory management staff” because it tells us what to record as data (profiles) but although we can say “interview the inventory management staff” we now have no idea what data we are looking for.

It is an idea if the activity is just one verb and list of useful verbs can be found in Workbook 16. One needs to be careful here that the activity is clear since almost all verbs need to be qualified or supported by stating their object. For example, if I were to say, “look at fault logs for my primary data” then that is very indistinct because it does not tell us what to look for (the object of the looking). But if I say, “look at fault logs to describe instances of SPAM attacks” then I now have a more distinct activity because I know what I am going to write down as my primary data. The whole primary data collection process is then fitted around that basic activity and the spotlight described below.

Primary Data Spotlight - The core of this primary data generation process is to find an activity which we can use to extract data and coupled with that we must have a primary data spotlight (usually we just say spotlight) that is focused and illuminates just the primary data that you want.

As an example, suppose the problem theme is the value of IT training. Clearly a lot of money is spent on training so it might be really useful to know if there is a link between it and productivity. Suppose we speculate that the link is to do with essential business working practices and these change over time to meet new needs so that what I need is an outcome in the form of a process model on how one identifies changes in business essential working practices and links them to a training initiative.

Now that I have my outcome as a process model the activity (BAGeD) can become **describe changes in essential working practices** of key operational staff – thus, my activity is “**describe**” and the primary data spotlight will be **changes in essential working practices**. Now that I have this core activity and spotlight I can work out the full process of getting to the data and processing the resultant collection to get my process model (outcome) that describes the link between business essential working practices and training.

Once the activity and spotlight are clear it is an easy step to say how that data will be collected. In the above example I might use interviews with relevant staff. In summary the whole process becomes **describe** (activity) **changes in essential working practices** (spotlight) using **interviewing** (collection protocol) with relevant staff.

6.10 Getting an Activity and Primary Data Spotlight

This can be quite hard to do but it is essential to find this activity and spotlight. So we are looking for an activity and we hope that activity can be used with the spotlighted data. There are only three real considerations:

Problem Area Expertise – it is obvious that you need to have gained expert knowledge in the topic area and in the particular aspect related to the problem theme you are dealing with. Unless you have thoroughly prepared by using literature reviews and/or other means you will simply not be in a position to know enough to be able to decide competently what data it is possible to collect.

Intended Outcome – fix in your mind that you are trying to generate as an outcome and recall that whatever primary data you collect will be first formed into a structured collection during the pre-processing phase, which follows immediately after collection, and then that structured collection will be used to generate, in some defined manner, your outcome.

Let us suppose the outcome is to be a set of guidelines, so you have to think what sort of primary data is needed to be able to generate the guidelines and that might be to look at current practices. Once we have the data on current practices we can move on to finding out how to generate guidelines from that data. This means you must know what a guideline is and how one is constructed and that is where secondary data comes in. So in this case you might look at text books or journal articles to find a guideline model to use. Additionally, you would look at examples as well as look at any relevant company or international standards.

Collection Protocol – the last thing to consider is can the primary data be collected and if it so, what is the best way to do that. So it's not a matter of just choosing anything that comes to hand, it is a serious practical consideration based on a thorough and logical analysis of the sort of primary data that you want.

In the guidelines example above, the idea might be to use a questionnaire and one has to ask would a questionnaire allow for the collection of the data I needed. Let us suppose that the data we spotlight is related to finding guidelines for IT media and usage. Now a questionnaire can easily get media data but it is not clear how it could capture usage data so I might decide to get that information by interview instead because I want a richer picture there - guidelines are largely about usage so that is where I must direct my effort.

To elaborate, usage is a complex issue and if you try to get it with a questionnaire you must have a very good idea what the usage processes are otherwise you may miss lots of things that are going on in the company setting. Whereas, if I use an interview, I have much more opportunity to explore the usage idea and that is what I really want.

6.11 Problem, Outcome, Activity and Spotlight Examples

Consider the following further examples which focus on the activity and data spotlight and its link with some theorising or speculation about an expected project outcome. In each case several possible outcomes are listed but in a research study only one would be chosen for further work.

One needs to be careful – this all sounds fine, even simple but a researcher must seriously consider if a complete process built around the activity and spotlight can be formulated in order to get at the necessary primary data within the time and other resources that are available.

Problem - Loss of competitiveness in Hong Kong SMEs

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A list and description of investment constraints or
- A strategy to deal with the investment constraints or
- A feasibility report on e-application implementation or
- A post implementation review report or
- A prediction reacted to the effects of the constraints

Let us suppose that I choose a list and description as my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on reviewing (activity) investment plans and the corresponding strategic plan in order to describe (spotlight) an investment constraint (Generated Primary Data). So my primary data will consist of a list of identified and defined investment constraints.

Problem – Data losses associated with non-effective IT business systems

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A process of data criticality categorisations or
- A user guide to data criticality or
- A DRP/BCP policy document or
- A report explaining how data and criticality are related

Let us suppose that I choose a DRP/BCP policy document my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on listing data categories and using these categories I review reported critical incidents related to data categories (spotlight) in order to match (activity) the category to the criticality of the incident (Generated Primary Data). So my primary data will consist of a list of categorised critical incidents.

Problem - Supplies continuity in manufacturing systems

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A evaluation of a modern supply change process or
- A feasibility report on RFID or
- An implementation plan for RFID or
- A model that shows how improvements may be made using RFID

Let us suppose that I choose to list and describe expected benefits of RFID as my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on describing (activity) supply chain (spotlight) tracking problems (generated primary data) and by a process of evaluation of each problem theme I suggest how it might be alleviated by RFID and hence an implied supply chain benefit. So my primary data will consist of a list of categorised problem themes in supply chain tracking.

Problem - Business productivity in sales staff

This might be resolved by any of the following outcomes if used by an appropriate situation actor.

- A feasibility study on IM and its use in offices or
- The definition of a training programme or
- A series of factors that must be in place before IM adoption or
- A cost/benefits report on Instant Messaging Technologies or
- The design of a regular monitoring scheme to assess effectiveness

Let us suppose that I choose a cost/benefit report as my project outcome. Now I have to find a way of getting at the data I need – activity and spotlight. So I decide to focus on analysing (activity) call content (spotlight) to identify the sort or calls and then extract the cost (generated primary data) and assess the sales benefit and by process of evaluation arrive at my cost/benefit report on IM technology. So my primary data will consist of a list of calls and their associated cost and sales benefit.

6.12 Writing an Hypothesis

Hypotheses are not always needed but if used they must match your research question and amounts to you saying what you think to be true in a given situation. When you do this your work then become a process whereby you try to show that your hypothesis is valid. There are three stages: firstly write the null hypothesis, secondly write the alternative hypothesis and lastly write down the dependant and independent variables. Unfortunately many new researchers seem unable to do the last part of this process. Let me illustrate.

A student wanted to write a hypothesis that essentially said that there was a link between IT certification training and personal productivity in support roles. He then went on to define the variables as: Role of IT (independent) and Personal Productivity (Dependent). Now this will ONLY makes sense if you can quantify the variables productivity (which is quite easy) and 'Role of IT' which it seems cannot be quantified.

In research people tend to treat the idea of hypothesis in two ways and the second way is often quite valuable in many research situations.

6.12.1 Formal Experiment

To set up a formal experiment one creates or identifies two samples: one exposed to some effect and one not. For example, suppose I were looking at whether a new diet called lose-weight-quick worked or not. I could set it up a hypothesis and look for samples where some people were exposed to the new diet and some were who were not. The experiment then amounts to seeing if there is any significant difference between these two samples. (See CN.001 Notes for how to set up a formal hypothesis)

In a sense we are trying to prove the diet works but that notion of proof needs very careful understanding. The point is that it is very likely that the diet will work for some in the sample and not for others. So our proof carries a qualification which is that all we could reasonably say at the end is that the diet is likely to work for a large number of people (or not as the case may be). A second point is that we do not usually do thousands of

similar experiments and so at best our results for a limited sample would be tentative. Notice that this outcome is quite different from an experiment that sets out to verify a natural law like Archimedes principle or Ohms law where the amount of variety is much, much less and of course such natural laws have been tested many thousands of times so we are assured of their validity.

Strictly, proof means that something is true for everyone, for all time and everywhere and it is obvious that that kind of proof is very hard to construct in technology. What we therefore tend to do is not to use the word proof but rather say that our research “indicates” that something is generally true. So for example, it is impossible to prove (for everyone, everywhere and for all time) that CRM system bring productivity benefits at low cost but our research might be able to indicate that this is often the case for those who use it.

6.12.2 Informal Idea

Instead of using a formal null hypothesis we could just have what might be called a tentative hypothesis that suggests that there may be a link and then use case studies, surveys, quasi-experiments and so on to demonstrate this. Notice that we are NOT proving anything here only suggesting that something may be generally true within certain parameters.

6.13 Writing an Aim and Objectives

For each project we want one overall aim and a set of objectives that collectively will generate the project outcome. An aim/objective is expressed as an activity to get a defined and measurable outcome within the scope of the project. The essential difference is that the aim expresses the target (or purpose) for the whole project outcome whilst objectives generate minor project outcomes that collectively allow us to eventually generate the project outcome and hence achieve the target.

6.13.1 Project Aim

This derives from the Research Question and is best thought of as expressing the overall activity and intention of the project to generate an outcome that can be placed in the project document or made easily visible to the examiners.

You will note in the aim structure that follows that the problem theme is not usually explicitly mentioned and we infer what it is by looking at the target. The reason it is not included explicitly is that when one does one tends to get very awkward constructions linking problem and target so we might see absurdities such as “to improve website accessibility because web site accessibility is problematic”.

The most common aim structure is as follows where project outcome is its most essential part because this is what the whole project effort is intended to generate. The structure can be remembered by using the acronym AOST.

Activity – what principal activity will be used with the available data to get the project outcome? Ideally, look for a single activity that sums up the whole project process for generating the intended outcome.

Outcome – this element says how the project outcome will be expressed knowing that this outcome will later be used to generate the real world target. What ever you say here **MUST** match with whatever outcome you state everywhere else in your specification.

Spotlight – where will the basic data used by the activity come from?

Target – what is the real world intention? That is the project outcome should be useful in the sense that it addresses the real world problem theme on which the project is based.

Aim – to create (**activity**) a website structure design (**outcome**) using cascading style sheets (**spotlight**) in order that it might be used in design to improve web site accessibility (**target**).

Sample Faulty Aim 1 – “To create an improved network infrastructure”. This is unsatisfactory because we have no target - we know that there will be an improved infrastructure but we don't know what effects that will have. So is improved infrastructure the outcome – it cannot be because it would imply sending to Portsmouth for marking some object called “improved infrastructure” and that is an absurdity. So here we have no target and no outcome and we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

So if I just use the above example it would be possible to have a target of a reduced network down time because of the Improved network infrastructure but that could **ONLY** happen after the project completes and in the project one could generate an infrastructure design - now that can be completed within the

project period and later used to build the infrastructure which can then be used to generate our reduced network down time. Another factor here is that we cannot measure whether something called improved network infrastructure (what scale would we use?) has been achieved unless we have a target such as reduced down time which of course we can measure.

Sample Faulty Aim 2 – “To build a Wi-Fi implementation strategy”. This is unsatisfactory because although we know the project outcome is an implementation strategy we do not know what value it has in the real world because we have no target. Notice also we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

6.13.2 Project Objectives

The aim expresses the project outcome but to get there we normally have to pass through a number of minor outcome milestones on the way and these are expressed as being generated by objectives. Since we are looking for minor project outcomes milestones that collectively deliver the project outcome we have a little problem here because any project is made up of a series of tasks from generating page footer to evaluating the project outcome. It follows that some tasks will generate a minor project outcome and some will not.

Objectives are not the same as making a project plan because they are ONLY concerned with activities that generate a minor project outcome - a schedule of interviews is a project activity but that schedule can hardly be regarded as a project outcome, it is just a step along the way to getting the primary data – so one might add that into the project plan but it would not be written as objective.

The structure and features expected in a well-written objective are as follows where you can use the acronym AMSB.

Activity – Ideally we look for the principal activity that will generate a minor project outcome that can be expressed in a form that can appear in the project document.

Milestone – in this feature you state the milestone as a minor outcome, knowing that it must be in a form that can be written into the project document and represent a sequential step building toward getting the final project outcome.

Spotlight – what is the data area focus of the objective's activity?

Bounded - objective outcomes must be achieved and available within the project period and must not refer to anything that might occur after the project document is completed and submitted

Example – To explore (**activity**) and model (**milestone**) the current software development process (**spotlight**).

This is **bounded** because we can do it within the project period and it is also a **milestone** (building block if you like) leading to my project outcome of a best practice portfolio in software construction.

It is easy to become completely muddled with objectives and one source of this muddle is the distinction between a project objective: something that a student can do and evidence in the project document and operational ones: something that has a real world effect that might happen after the project has been completed. In simple terms if you set an objective in your project it must be completed within the project time scale. Let us just take an aim and look at some possible objectives.

Aim = To survey (**activity**) workers in Southampton (**spotlight**) and report (**outcome**) on how they use the bicycle as an aid to mobility (**target**) in a modern urban environment.

Sample Objective 1 – “To identify and list (**activity**) in a report (**milestone**) the components of a modern bicycle (**spotlight**)”. This is fine since clearly it is something that you can do, evidence in a project document so somebody else could check what you have done and it is clearly bounded.

Sample Objective 2 – “To describe (**activity**) how a bicycle functions”. This is no good since although it is clear that you can develop a description, no one can check it unless you write it down and it is not clear where we would look for the data. Better to say “To describe (**activity**) by means of annotated diagrams (**milestone**) how a bicycle functions by observing it in use (**spotlight**)”

Sample Objective 3 – “To understand (**activity**) how a bicycle helps urban workers (**spotlight**)”. This is no good because there is no clear spotlight so there is nothing to focus ones understanding on and even if

there were no one else can check your understanding because there is no milestone. Better to say, "To prepare (activity) a report (milestone) explaining how urban workers could be helped by the use of a bicycle in their daily lives by examining typical patterns of mobility for office workers in Southampton".

Sample Objective 4 - "To ensure (activity) that workers get to their office on time by using a bicycle". This is no good because there is no way anyone could do this activity and if you cannot do it no one can check what you have done. It also sounds more like an aim than an objective because it hints at a target. Better to say "To report (activity) on bicycle usage strategies (milestone) that might be applied by urban workers to ensure they get to work on time by identifying and observing regular cyclist's usage profiles".

Sample Objective 5 - "To implement (activity) a bicycle repair system". This is no good because although it is obvious you can do it, it cannot be checked in your project document because it is an operational activity and not a milestone that can be documented. But you could say "To produce (activity) a design document (milestone) for the creation of a bicycle repair centre by examining manufactures basic requirements for business applications of this nature (spotlight)".

Sample Objective 6 - "To ensure (activity) that bicycles conform to BS 7898 (spotlight)". This is not really much good as it is in essence a requirement and not something that one can do within a project itself. However, one might have written "To evaluate (activity) and report on infrastructures (milestone) necessary to achieve BS 7898 compliance requirements (spotlight)".

6.14 Writing a Title

The title is the name of your project – rather like the name of a novel, something that catches a potential reader's attention but just gives a hint as to what the work is all about. Think of it as a kind of nickname or slogan for your project and as such it is not a good idea to try to use the same set of words for the title, Research Question and aim. Titles typically have two elements:

Aspect – this is the particular focused area of you study

Why – this says why it might be a useful aspect

Mentioning the means by which you solved your problem should only be included in the title if it is crucially important. As an example, suppose your project was concerned with the development of a database and you used Microsoft Access. Unless your project compared your product with a similar database implemented in Oracle, say, then the tool you used to solve the problem is not as important as the problem you set out to solve.

Be careful with titles, there is a tendency to use the title to say what you will do. The purpose of the title is to give a concise name to what you do. Avoid noise words or phrases such as: "A report into..." (redundant: of course it is a report!) or words like "study", "investigation", "enquiry" and "development" are often similarly just noise. It is also usually very unwise to express the title of your project as a question although a title in the form of a proposition is often quite useful as in example 1 below. Here are some examples of good titles:

Planar Similarity – A Possible Software Quality Measure
Heuristics in the Stages of Soft Systems Methodology
A Taxonomy of Heuristic Problem Solving

7. WORKBOOK 7 – BASIC RESEARCH METHODS CHECKLIST

The work book is all about being able to select a research/problem solving method that fits the sort of research study you are engaged in. In every case you will have to decide what data you want to collect and choose rationally a research method (problem solving method if you like) as your primary research vehicle and build a research design around it.

You need to exercise care here so as not to become confused between a Research Method, which is a framework or model for the whole research project such as survey or action research, and Data Collection Protocols, which are vehicles for actually collecting the primary data and might include such things as interview, observation, questionnaire, seminar or role playing. However, before looking at these research models it is useful to just review basic research styles and approaches.

7.1 Research Styles

This is a practical notion and you would be wise to think project ideas through in terms of these styles. There is no sense that one or other is superior and no reason why both should not be applied at the same time.

Quantitative – a style that represents information in numerical form. The numerical form might be graphs and statistics which can be used to show trends, comparison and similarities and the graphs might lead to equations which link variables or allow one to make generalisations.

The advantage of quantitative data is that there is solid evidence that can be permuted in a variety of ways to support or not support a contention. In general, one is counting the frequency of some event – say the number of times the user selects the wrong icon but, and it's a big but, the data is only truly valid in the context in which it was collected so one needs extreme care if we want to generalise.

Qualitative – a style typically used to analyse how certain actions occur not just how often they occur. The information is usually represented in textual form of some kind as a description of some observable event or events. The usefulness of this is that it exposes the thought processes or reasoning behind a particular behaviour – why a user clicked the wrong icon. However, it does make the analysis and representation of the data more complex.

Although these are defined, in practice one does not usually start by thinking about the style and typically as you think about the problem and what primary data your research will collect to deal with it then it tends to define itself as predominantly quantitative or qualitative.

7.2 Research Approaches

There are two broad approaches to research, which is always essentially exploratory. In practice you do not decide the approach as such and it will effectively be decided for you when you formulate your research problem and construct your research design. However, we may loosely define:

Deduction - This means inferring particular instances from a general law. So if for example we use Ohm's law to predict with certainty the value of current if we know the resistance and voltage applied to a circuit. In technology I might want to look at the significance of scripting languages on system development time. I could do this by setting up a null hypothesis that says 'I contend that the use of scripting languages have no effect on system development time' so in effect I am suggesting a law here.

Inductive - This means the inference of a general law from the observations of particular instances. For example, you notice something that happens and see that it happens often. It follows that you can infer a general law from your observations. For example, you notice that people in your company tend to be more productive after IT training so you then make a generalisation using induction and say "training in IT leads to personal productivity increase".

It is very important you understand that nothing has been proved here and all you have is an indication. It is not a proof because we cannot know what new tasks or technologies might occur in the future. One of the greatest modern philosophers, Popper, put it like this. "you can never accurately predict the future because it is impossible for men to know now what they, or others men, will know in the future". It follows that we are never possessed of the data that can allow us to make certain predictions about what may lie over the horizon based on our current stock of knowledge.

In research we might think along either of these lines so for example we often set a hypothesis (a guess at general law) and then try to prove it. Alternatively we can go and collect data and by looking at the data see if we can work out what the law involved might be.

There is no right/wrong approach and it's a matter for you to consider what sort of outlook you are taking although in technology we tend to take an inductive attitude. It may sound simple and often no matter what our stance we end up collecting the same data but it will not always be simple – supposed you were looking at the effects of system migration in a rapidly expanding company and project control methods then it is not obvious what the link between these two things might be so a deductive stance would be unsuitable here.

7.3 Research Outlook

Before we look at the various research methods it is useful just to records that there are two outlooks that are available to a researchers.

Hypothesis Driven – this is the classical research paradigm where we have by some means devised a theory or speculation of some kind and the research is then directed at trying to show that the theory or speculation is valid. For example, we might theorise about who buys Gel Pens and then try to show that it is true, or more usefully try to explain in a report why it is true

Data Driven – it often happens that when we embark on research we don't have a hypothesis which we are setting out to test. This is very common today where corporations have vast databases and want to see if there is anything useful in them that might for example lead to competitive advantage. It follows, that in these cases we don't start with a hypothesis but we examine the data sets looking for patterns or outliers or indeed anything that might allow us to formulate a theory of some kind. For example, we might look through millions of sales transactions and then to hypothesise that people who buy Gel Pens all have beards and wear dark glasses. If this theory is true we can better target our Gel Pen products.

7.4 Which Research/Problem Method to Use?

There are many methods/models that we use for setting up research, the most common being: case studies, vignettes, action research, experiments, surveys, biographies/histories, grounded theory, ethnography and requirements gathering. It is never easy to decide on a method or perhaps more than one method.

Usually in research we do such things as: understand, explore, describe, explain, illustrate, improve, build something or prove something. It is therefore very important when you are trying to decide on a method to keep this basic purpose uppermost in your mind.

Choosing a research/problem method will depend on many factors such as: context, available literature base, basic research purpose, is the domain changing rapidly, time available, skill available, sampling and other practicalities, access, your personal stylistic inclinations, reason for the study, what kind of outcome you want, cost, quantitative/qualitative, scale, control, sensitivity of the data and so on. Notice these factors are almost all about practicalities - a design has to be used and that means it has to be practical.

7.5 Rationale: Case Studies

The case study method focuses on just one, two or twenty examples – such as your place of work, or one element of your organization or several aspects of a problem area. Typically:

1. Case studies are commonly used to **illustrate** or **understand** a problem or **indicate** good practice.
2. Case studies always have a context so make sure you are aware of it.
3. Case studies are usually qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain or describe some activity or phenomena.
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. There are broadly speaking two ways to begin case studies. This first is that you can set criteria and then go looking for relevant cases or secondly you can design and create the cases.
7. For most case studies there is usually be a longitudinal element - that is the cases will run over a fixed time period and you will periodically visit each case to collect the data.
8. There are several kinds of case possible:

Unique – implying that the setting and context are extremely rare and there may not be another chance to study this problem area again.

Critical – implies an important theory that you want to test and a particular case fits that profile.

Representative – implies that the case profile represents a typical or everyday situation.

Revelatory – implies that the case profile allows a researcher to study a situation never before looked at in detail and its context may be common.

9. In practice you can use the following to organise your cases but remember once you have your case design you will need permission from whoever is necessary.

How many cases – be practical because there are time limits.

Case Criteria - add as many criteria as you think necessary to pin down the data location but don't have so many that you will never find a case that fits.

Sample criteria (collection protocol) – add as many criteria as you need to pin down a particular sample point where a unit of data can be obtained.

Visit Frequency - each case must be visited to get the data so work this out by looking at how much total time is available for the study.

Data collection Vehicle – by observation, interview, document analysis, etc. You will have to have a protocol to say when a valid sample arrives.

7.6 Rationale: Vignettes

These are perhaps best thought of as micro case studies or snapshots that illustrate just one idea and almost always are qualitative in their application. Typically:

1. Vignettes are commonly used to in research contexts where actions, motives and judgements are to be explored, often in sensitive situations and you want to extract and **describe** examples or **illustrations** of significant elements in that problem domain
2. Vignettes always have a context so make sure you are aware of it.
3. Vignettes are essentially qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain, test and idea or describe some activity or phenomena.
5. Typically you cannot control and indeed have no desire to control the events being looked at but the events should be contemporary.
6. Vignettes enable participants to define the situation in their own terms or for their needs.
7. Most vignettes are "one off" events and as such act as indicators of an idea rather than as some sort of proof of concept. Therefore, this may also be useful when only a small sample is possible.

7.7 Rationale: Action Research

The main purpose of action research is to improve identified practice in some way. Typically:

1. Action research is commonly used to conduct research at the workplace with a strong desire to **improving** aspects of your own or colleagues' work so
2. In this kind of research you must be in control of events and they must be contemporary.
3. Typically indicated as useful when the research question starts with 'how' and there is a desire to explain something and use that explanation to improve practice.
4. Because of its setting, it is obvious that the research design is linked closely to its context.
5. The whole point of doing action research is the research leads to change in practice.
6. The working strategy is: plan something, do something, observe the something and reflect on what has happened as a result of your actions.

7.8 Rationale: Experiments

This form of research is used where there is a hypothesis and an associated variable that you can control (the independent variable) that will produce a change in some other variable (the dependent variable). That is the whole idea implies that you can intervene by altering or controlling the independent variable. Typically:

1. Experiments are commonly used when you want to **prove** or at least **indicate** that something is true. In practice proof is very difficult as it would imply that you findings are true for everyone, everywhere and for all time and so then tendency is to say indicate rather than prove in most cases.
2. In very simple terms one forms two groups: one which is exposed to the intervention and one which is not and then we observe if there is any difference because of the intervention.
3. Typically indicated when the research question starts with 'how' or 'why'.
4. The researchers must be in control of the events being looked at and they must be contemporary
5. The biggest risk is that there may be other variables involved which we are not aware of.
6. It is difficult to be sure that our sample is representative.

7.9 Rationale: Quasi-Experiments

This form of research is used where there is a hypothesis and associated variables but you cannot control any of them. It would be nice to think we always had time and resources to run a carefully designed experiment but unfortunately this is often not the case. In an experimental design one chooses the samples involved randomly and thus one has control. However, it may be that data already exists and you can test your theory on that existing data or it may be that you simply cannot get control over all the variables that you want. So an experiment and a quasi-experiment are very similar it's just that the quasi-experiment does not quite have all the trappings that a full experiment has.

7.10 Rationale: Surveys

This form of research is used when we want to ask a group of people a question or questions. Typically:

1. Surveys are commonly used when one needs to get and express an overall **understanding** of the properties in a given domain.
2. One could of course also survey 'things' as well as people.
3. Surveys lend themselves to future replication.
4. Typically indicated when the research question starts with 'who', 'what', 'where', 'how' many' and 'how much'
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. Questions must be well-designed and unbiased and may be asked by interview or questionnaire.
7. Be careful to distinguish questions that are asking for facts and questions that are asking for opinion
8. The results will be very dependant on having a big enough and representative sample.
9. Be clear as to how the data will be collected – by observation, interview, questionnaire, etc. You will have to have a protocol to say when a valid sample arrives.

7.11 Rationale: Biographies/History

This form of research is used when we want to trace an historical event and analyses/evaluate its history as this may lead to insights or explain certain action so that lessons may be learned.

1. Biographies/History are commonly used to form a **description** and **explanation** of events.
2. One can use this to look at individuals or organisations or even technology.
3. Typically indicated when the research question starts with 'what'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. Be clear as to how the data will be collected – by documentary study and interviews are common.
7. Histories are naturally chronological and are characterised by epiphanies (pivotal events) and almost always exists in a context.

7.12 Rationale: Grounded Theory

Here the main idea is to use research to arrive at a theory based (grounded) on collected data. Grounded theory is quite difficult to understand and practice.

1. Grounded theory is used in situation where the theory is unclear or even unknown and so there is a need to **explore** seeking **description** and **explanations** in a domain.
2. One can use this to look at organisations or technology.
3. Typically indicated when the research question starts with 'why'.
4. You cannot control the events being looked at but the events need not be contemporary.
5. This is typically a qualitative study.
6. Be clear as to how the data will be collected – by documentary study, interviews, questionnaires etc.
7. Grounded theory is systematic in that the idea is to gradually move closer to a position where we can suggest a theory or proposition.
8. The basic unit of research is the category which is something that may represent a unit of information and might be almost anything.
9. The essence of grounded theory is in its data processing where various forms of coding are used to gradually unlock meaning in the data.

Open Coding – essentially the formation of the initial categories of information – it is characterised by looking for properties or asking when the something is a dimension of the research space.

Axial Coding – this is about trying to assemble that data after open coding. This can be done by using a diagram or some logic that connects things or looking for causes or looking for contexts and consequences.

Selective Coding – here the researchers invents a plausible storyline that integrates the categories in the axial coding model.

Matrix – a final step (though often omitted) is to produce a conditional matrix that is supposed to make clear the social, historical, technological or economic conditions that prevail in a situation.

Theory – one hopes that as a result of all this processing a theory will emerge which of course may go on to be tested by a formal experiment.

7.13 Rationale: Ethnography

This form of research is used when to immerse ourselves in the day to day life of an organisation or group. In this context ethnography is a description and interpretation of a cultural or social group.

1. Ethnography is commonly used when we want a reflective **description** expressed in an **interpretive** manner.
2. One can use this to look at individuals but more typically organisations.
3. Typically indicated when the research question starts with 'why'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. You may alter the events being looked at because you are normally a participant observer.
7. Be clear as to how the data will be collected – by participant observation.
8. Ethnography is about immersion in a culture: behaviours, language, structures and functions.
9. In such studies one often encounters gatekeepers, key informants and communication relies on a sense of reciprocity by investigator and his subjects.

7.14 Rationale: Requirements Gathering

Requirements are simply a statement of a systems service (what it must do) or constraints (what it does not necessarily do). In practice saying what a system must do is often extended to how it will do it. This method is a form of action research but it differs in that the only contact one has with the people involved is at the requirements stage and possibly at the implementation stage though this may vary depending on the systems life cycle employed. You should use this method when you are setting out to build an application of some kind such as a computer application. There are 4 stages of requirements.

Functional Requirements - These are requirements that say what a system does or is expected to do. Typically this would involve or include most of the following: process descriptions, details of all inputs/outputs and details of all the data that must be held in the system.

Performance Requirements - This is usually understood to mean requirements that describe aspects of the system that are concerned with how well it provides the main functional requirements. For example: performance criteria such as response times or how long it takes to print a report, data throughput and storage needs and security considerations.

Technical Requirements - This aspect of requirement looks at the tools and method used to build the system. For example, it may happen that you have to use a certain database package or for other reasons you need to select a particular scripting language and so on. More often than not this aspect amounts to looking at technical constraints that must be applied in building the system.

Usability Requirements - Requirements that ensure that there is a good match between the system and its users. In most cases usability is expressed in terms of measurable objectives.

7.14.1 The Requirements Document

The system and software requirements are usually documented in a formal manner so that ones understanding may be communicated to customers and system builders. The requirement document describes the following:

Services and Function – that the final system must deliver.

Operational Constraints - under which the system must operate.

Development Constraints - on the process used to develop the system.

Properties of the system - in the sense that it may have unplanned additional functionality.

Links - definition of other systems with which the system must integrate.

Domain - Information about the application - for example how to carry out certain tasks.

Definitions – acronyms, abbreviations etc.

7.14.2 Stakeholders

These are people who will be affected by the system and therefore should have a direct or indirect influence on the system requirements.

7.14.3 A Process Model

As a process model we might define the requirement process as follows.

7.14.4 Requirement General Questions

There are perhaps four general questions we might ask when attempting to gather requirements

Problem - What are the problems with the current processes?

Improvements - What are the improvement goals?

Reference. Kotonya, G. and Sommerville, I, (1997), Requirement Engineering, Wiley, ISBN 0-471-97208-8. This book is useful because it also contains excellent reading and reference lists.

7.15 Research Design

Finally, you must set out your research design. That is, explain how you will get your data – and this must be done in great detail. In summary, then, your research design is the blueprint of your research project which enables you to deal, systematically, with:

What questions to study?

What data is relevant?

What data to collect – you will need to work very hard here so that you can rely on your data.

Are there any practical limitations to what you can do

How to analyse the results – don't shirk this.

How to decide in which contexts your findings are applicable or can be exploited.

The main purpose of your research design is to help you avoid a situation in which the evidence you eventually collect does not address your initial question.

7.16 Research Process Development

It is quite common is many kinds of research but notably in Case Study and Action Research for the researcher's perceptions to change as data emerges. Often this will imply that the research design has to be changed or amended if it is to remain meaningful. These changes may be small such as a slight modification to the Research Question or aim but occasionally it may be necessary to make significant changes. For this reason researchers must always be careful in their design to allow a little flexibility if they can to accommodate possible unforeseen circumstances.

8. WORKBOOK 8 - BIBLIOGRAPHIC REFERENCING HARVARD APA

This workbook is a short summary of the APA style guidelines as contained in The Publication Manual of the American Psychological Association, 5e, 2001 (Subject Reference Collection: 808.02 AME).

The APA style is based on the Harvard referencing system whereby the date of publication follows the author name(s), and in-text references refer to items in the reference list using the author surname and date of publication, in brackets.

Referencing is important in all academic work as it indicates to the reader the sources of your quotations and borrowed ideas. Failure to indicate your sources is tantamount to plagiarism (literary theft). The purpose of the referencing system is to describe your sources in an accurate and consistent manner and to indicate within the text of your paper where particular sources were used.

Please note that there are two sections to this document:

How to **reference** correctly a source in the **bibliographic** section of your work

How to **cite** correctly a source in the **written** part of your work

Don't Get Caught Out! If you do not reference correctly you may lose marks or your work may be returned unmarked to you for correction. Therefore:

Keep a careful note of all sources used as you prepare your assignments.

Record all the details you need about a library book (including page numbers for any quotations) **before** you return it - someone else may have the book if you try to go back and check later.

Make sure you write down the source details you need on any photocopies or downloads you make.

Remember to print or save details of any website you want to refer to and record the date when you accessed the information.

8.1 Reference list (Bibliography) at end of Project/Dissertation

The reference list should be arranged alphabetically by author surname. The APA format requires book and journal titles etc. to be italicised, although we are not strict about that.

As a rule in projects and dissertations it is normal to produce two lists. The first is a reference list and that **MUST** only include sources you have cited. The second is a bibliographic list which includes all other sources you might have found but did not cite – this list is to allow the reader to explore the topic further if they wish.

8.2 Books

The details needed for a book can normally be found on the front and back of the title page. Make sure you locate the name of the publisher rather than the printer or typesetter. You need the name of the publisher in your reference list. Ignore any reprint dates; you need the date when the first, second, third edition etc. of the book was published according to which edition of the book you are using.

8.3 Journal articles

The details needed for a journal article can usually be found on the contents list, front cover or article itself.

8.4 Printed publications: Examples of References

The following are sample if how to correctly reference a source.

Book – pattern: Author, Initials. (year). Title of book. Place of publication: Publisher.

American Psychological Association. (1994). Publication manual of the American Psychological Association 4e. Washington, D.C.: Author.

Encyclopedia of psychology. (1976). London: Routledge.

Gardner, H. (1973). The arts and human development. New York: Wiley.

Moore, M. H., Estrich, S., McGillis, D., & Spelman, W. (1984). Dangerous offenders: the elusive target of justice. Cambridge: Harvard University Press.

Strunk, W., & White, E. B. (1979). *The elements of style* (3rd ed.). New York: Macmillan.

Note: Only list up to 6 authors. The 7th and subsequent authors are abbreviated to et al.

Edited book

Maher, B. A. (Ed.). (1964-1972). *Progress in experimental personality research* (6 vols.). New York: Academic Press

Article in edited book (Chapter) - The basic pattern for a reference to a chapter in an edited book (where the chapters have been written by several different people) is:

Author of chapter, Initials. (year). Title of chapter. In Initials. Name of Editor/s (Ed.) *Title of book* (pp.start and end page numbers of chapter). Place of publication: Publisher.

Vygotsky, L. S. (1991). Genesis of the higher mental functions. In P. Light, S. Sheldon, & M. Woodhead (Eds.), *Learning to think* (pp. 32-41). London: Routledge.

Encyclopedia entry - If the entry has no author, begin the reference with the entry title followed by the date of publication.

Lijphart, A. (1995). Electoral systems. In *The encyclopaedia of democracy* (Vol. 2, pp. 412-422). London: Routledge.

Government publication

Great Britain. Command Papers. (1991). *Health of the nation* (Cm 1523). London: HMSO.
Great Britain. Home Office. (1994). *Prisons policy for England and Wales*. London: HMSO.

Report

Birney, A. J., & Hall, M. M. (1981). *Early identification of children with written language difficulties* (Report No. 81-502). Washington DC: National Educational Association.

Conference paper in published proceedings

Borgman, C. L., Bower, J., & Krieger, D. (1989). From hands-on science to hands-on information retrieval. In J. Katzer, & G. B. Newby (Eds.), *Proceedings of the 52nd ASIS annual meeting: Vol. 26. Managing information and technology* (pp. 96-100). Medford, NJ: Learned Information.

Journal article - The basic pattern for a reference to a journal article is:

Author, Initials. (year) Title of article. *Title of journal*, Volume number - if there is one (Issue number), start and end page numbers of article.

Noguchi, T., Kitawaki, J., Tamura, T., Kim, T., Kanno, H., Yamamoto, T., et al. H. (1993). Relationship between aromatase activity and steroid receptor levels in ovarian tumors from postmenopausal women. *Journal of Steroid Biochemistry and Molecular Biology*, 44(4-6), 657-660.

Popper, S. E., & McCloskey, K. (1993). Individual differences and subgroups within populations: the shopping bag approach. *Aviation Space and Environmental Medicine*, 64(1), 74-77.

Weekly magazine article

Barrett, L. (2001, August 23). Daewoo's drive to survive in the UK. *Marketing Week*, 22-23.

Newspaper article

Caffeine linked to mental illness. (1991, July 13). *New York Times*, pp. B13, B15.
Young, H. (1996, July 25). Battle of snakes and ladders. *The Guardian*, p. 15.

Two or more works by the same author(s) with the same publication date - Where an author (or particular group of authors) has more than one work in a particular year, list them in title order and follow the date with a lower case letter a, b, c, ... For example:

Harding, S. (1986a). The instability of the analytical categories of feminist theory. *Signs*, 11(4), 645-64.
Harding, S. (1986b). *The science question in feminism*. Ithaca: Cornell University Press.

Anonymous works - If a work is signed "Anonymous", your reference must begin with the word Anonymous, followed by date etc. as normal. If no author is shown, put the title in the normal author position.

Note on source page numbers - Use pp. for page range only for encyclopedia entries, multi-page newspaper articles and chapters or articles in edited books. For articles in journals or magazines use the numbers alone.

Interviews and email messages - Because interviews and email messages are not considered recoverable data, you do not give details in your reference list. You should, however, cite an interview or email message within the body of your text as a personal communication: ...and this point was conceded (J. Bloggs, personal communication, August 22, 2001)

Legal References - Because the situation regarding legal references is complex and only US law is covered in the APA Manual, legal references will be covered in a separate guide.

Audiovisual sources: examples of references - Such sources are often complex but please note.

Films - The basic pattern for a reference to a film is:

Name of primary contributor - the director or producer, or both, Initials. (Role of primary contributor). (year). *Title of film* [Motion picture]. Country of origin - where the film was primarily made and released: Name of studio.

Reed, C. (Director). (1949). *The Third Man* [Motion picture]. United Kingdom: British Lion/London Films.

Spielberg, S. (Director). (1993). *Jurassic Park* [Motion picture]. United States: Universal Pictures/Amblin Entertainment.

If the film doesn't appear on the Library Catalogue, the Internet Movie Database <http://uk.imdb.com/> is a good place to check all the details needed for a film reference (follow the Company credits link to find details about the film studio/s involved). Alternatively, check Halliwell's Film and Video Guide.

Review of a film - If the review is untitled, put everything in square brackets in the normal title position and keep the square brackets.

Kinder, M. (2002). Moulin Rouge [Review of the motion picture *Moulin Rouge*]. *Film Quarterly*, 55(3), 52-59.

Malausa, V. (2001). Beauté du mensonge [Review of the motion picture *The Tailor of Panama*]. *Cahiers du Cinéma*, 558, 82-83.

Television programmes

Collinson-Jones, C. (Producer), & Dobson, E. (Director). (2003, July 14). Casualties of peace [Television broadcast]. London: Channel 4.

Single episode from a television series

This example shows the most complete information possible for a television episode. If details of the writer are unavailable, begin your reference with the name of the director.

Fraser, R. (Writer), & Geoghegan, S. (Director). (2003). Eyes wide open [Television series episode]. In P. Goodman (Producer), *Holby City*. London: BBC1.

Radio programmes

Portenier, G. (Producer). (2003, July 17). *Crossing continents*. London: BBC Radio 4.

Electronic sources: examples of references - The details shown below have been compiled according to the guidelines available on the APA Website (<http://www.apastyle.org>) in August/September 2001 (re-checked July 2003). Check this Website and the 5th edition of *The Publication Manual of the American Psychological Association* which is available in the Frewen Library for further guidance.

The basic pattern for a reference to an electronic source is:

Author, Initials. (year). *Title*. Retrieved month, day, year, from Internet address.
Banks, I. (n.d.). *The NHS Direct healthcare guide*. Retrieved August 29, 2001, from <http://www.healthcareguide.nhsdirect.nhs.uk/>

If no date is shown on the document, use n.d.

If the author is not given, begin your reference with the title of the document.

If a document is part of a large site such as that for a university or government department, give the name of the parent organisation and the relevant department before the Web address:

Alexander, J., & Tate, M. A. (2001). *Evaluating web resources*. Retrieved August 21, 2001, from Widener University, Wolfgram Memorial Library Web site: <http://www2.widener.edu/Wolfgram-Memorial-Library/webevaluation/webeval.htm>

Deciding your future. (2000). Retrieved September 5, 2001, from University of Portsmouth, Careers Service Web site: <http://www.port.ac.uk/departments/careers/plancareer/deciding-your-future.htm>

Electronic journal articles which are duplicates of the printed version - Use the same reference format as for a printed journal article but add "Electronic version" in square brackets after the article title:

Lussier, R. N., & Pfeifer, S. (2001). A crossnational prediction model for business success [Electronic version]. *Journal of Common Market Studies*, 39(3), 228-239.

If you are referencing an online article where the format differs from the printed version or which includes additional data or commentaries, you should add the date you retrieved the document and the Web address (URL).

Articles in Internet-only journals

Korda, L. (2001, July). The making of a translator. *Translation Journal*, 5(3). Retrieved August 21, 2001 from <http://accurapid.com/journal/17prof.htm>

Use the complete publication date shown on the article.

Note that page numbers are not given.

Whenever possible, the URL you give should link directly to the article itself.

Break a URL that goes onto another line after a slash or before a full-stop. Do not insert a hyphen at the break.

Articles retrieved from a database - Use the format appropriate to the type of work retrieved and add a retrieval date, plus the name of the database:

McVeigh, T. (2000, July 9). How your gestures can do the talking. *The Observer*, p.7. Retrieved September 10, 2001, from The Guardian and The Observer on CD-ROM database.

8.5 Citing references in the Text

There are basically two forms. The first is when the author's name is naturally part of the sentence and the second when it is just a reference. References are made from the text of the paper to the full details of the work in the reference list in the following manner:

It is a contention of the paper, and this contention is supported by Williams (1995, p.45) who compared personality disorders ...

When an author, or group of authors, has more than one publication in the same year a lower case letter is added to the date. For example:

In two recent works Harding (1986a, p.80; 1986b, p.138) has suggested that ...

With two authors both names should be listed in each citation e.g. Duncan & Goddard, (2003, p.99)

With three to five authors name all authors the first time, then use et al. (and others). For example: the first time it would be Moore, Estrich, McGillis & Spelman (1984, p.33) and subsequent references to the same publication would use Moore et al.

For six or more authors, use et al. after the first author in all occurrences.

Note that when the in-text reference occurs naturally within the sentence "and" should be used before the final author.

When a source has no author, cite the first two or three words of the title followed by the year. For example:

... in the recent book (*Encyclopaedia of psychology*, 1991, p.62) ...

... in this article ("Individual differences," 1993, p.12) ...

Web pages where no author is given

However, if the author is designated as "Anonymous", cite the word Anonymous in your text e.g. (Anonymous, 1993, p.116).

When using quotations in your text

Try to observe the following methods.

Gardner (1973, p41) stated that, "The relative importance of the systems may nevertheless remain in approximately the same proportion"

Smith (1991, p84) found that "...there is no evidence that chimpanzees can produce a drawing and discern the object represented in it..."

Occasionally, very occasionally you may need to cite a work that you discovered in another work because you cannot find the source then observe the following examples:

Smith (1970, p.27) cites Brown (1967) as finding ...
Brown (1967), cited by Smith (1970, p.27), found ...
It was found (Brown, 1967, cited by Smith, 1970, p.27) that ...

If you need to use this form your tutors must approve it and you must show that you have made every effort to track down the primary source.

9. WORKBOOK 9 – WRITING UP A RESEARCH PROJECT

This workbook is in several sections covering everything from project supervision to grading.

9.1 Your and Your Supervisor

The student supervisor relationship is very important if a high quality project is to be achieved. As a rule the supervisor will be interested in the topic area and will want to be active in its development although you as a student must do the work. However, your supervisor will not be expert in everything but will usually have some knowledge of simple statistics and the four main research methods: experiments, action research, surveys, case studies and application development.

9.1.1 Student Expectations

The normal expectation is that students have of their supervisor are as follows:

- Only be available for consultation for a limited time.
- Only supervise what the student does and not do the work for them.
- Advise on research design, scheduling and literature surveys.
- Advise on theoretical, conceptual and methodological issues.
- Advise on development of research skills.
- Advise on data collection, processing and analysis.
- Advise on ethical issues if they are relevant.
- Read, evaluate and be constructively critical of student work if given sufficient time.
- Have a good knowledge of the general area you are working in.
- Be in contact with the student regularly.
- Arrange if necessary supervision chat sessions.

For project students on distance learning programmes it will be possible to have meetings in the WebCT chat room, using IM or Skype where a full and detailed interaction can take place. These must normally be agreed with your supervisor and must be planned not to clash with other classes. However, some tutors may allow student to contact them any time they are seen to be online.

9.1.2 Departmental Expectations

Supervisors take a formal role and certain attitudes and actions are expected. In general they will:

- Visit the discussion board and email regularly within WebCT (at least 3 times per week).
- Set a mail forwarding address to their personal accounts in WebCT email settings.
- Devote at least 6 hours to the supervision process spread over the project duration.
- Conduct one-to-one chats as required with project students.
- Conduct student/supervisor communication within WebCT or their personal email account.
- Respond to a student query within a certain time frame (normally no longer than 3 days).
- Be familiar with all the project guidance notes and workbooks.
- Be familiar with the project chapter profiles.
- Make sure students know if they are to be away for an extended period.
- Be aware that students may make contact through any one of several WebCT accounts.

The essence of online supervision adequacy is based on the quality of communication between supervisor and student with the intent that we want the learning experiences to be exciting, stimulating and self-rewarding. In practice this means that communication must be frequent, lucid, critical and yet encouraging.

Supervisors should be aware that if they set email forwarding in WebCT they will effectively get an automatic alert when there is mail for them. If the student has also set mail forwarding then supervisors will be able to reply immediately otherwise they will have to go into WebCT. However, there is no alerting mechanism if a student posts a question into discussion so supervisors must visit the site from time to time so as not to miss any messages.

9.1.3 Supervisor Work Reviews

Supervisors will read your written work. However, when they do this certain rules apply:

Finished work – you should supply your supervisor with written work as it is produced chapter by chapter but it must be finished work. In this context finished work means that the format and content are the very best you can produce and in accordance to the guidelines found in this workbook. The tutor's role is not to act as some kind of filter for rough work or polishing multiple drafts which you want to improve in effect making them do the work for you. If a tutor suspects that the section you have sent in is not in its final form they will return it to you without comment.

Action on Feedback – if you are given feedback on any part of your work then you are expected to study it with care and commitment. However, it is up to you how to respond or even ignore what you are told but in all cases the consequences that follow are entirely your own responsibility.

Responding to Feedback – in all cases you are expected to respond to feedback. This may take several forms: writing to your supervisor saying that you don't agree with him or perhaps offering further explanation or as in most cases making changes to the content or structure of your project document. When you make document changes in response to feedback they are to be shown **shaded** so your supervisor can easily see exactly what you have added or amended.

Questions to Tutor - your tutor will not answer any questions regarding whether your work is right, wrong, is it a pass, what mark will I get or is it good enough. The only thing you can expect in this area is that you tutor may advise you that the work is not ready for submission to the university. If this happens it will be entirely your own decision whether to submit or not but if you do not submit a fail will automatically be recorded and you should be aware that extensions will not normally be given.

Response from Tutor - in most cases your supervisor will only suggest that you do something or ask a question designed to point you in a new direction. Normally, the tutor will not supply you with any project content since that must be provided entirely by you. The reason is that the work is yours not the supervisors.

Preparation - Your supervisor will expect you to be familiar with all the notes and workbooks contents. You should therefore be careful that you don't waste supervision time asking questions to which you already have the answers.

9.1.4 Chat Session

Chat sessions for project students will usually be one-to-one and typically used when there are particularly awkward difficulties – chat will NOT be the norm during projects and your tutor will have no expectation that chat will be used.

9.2 Overview of Project Structure

Here are some general guidance notes – they are NOT suggested chapters but general content guidance on the project as a whole and have a sharp process focus.

9.2.1 Introduction summary

This is about the problem theme and its setting, target, client context, topic area, personal theory, Research Question or application functional description and intended project outcome, general research orientation followed by a well-defined aim and sound set of objectives. The introduction is to be precise but concise taking a discussion form that is explanatory and focused on giving readers a clear, coherent and comprehensive view of what the project is about.

9.2.2 Preparation for Research

This is your study of the topic area and research methods that you will need to know about. You will have to justify and explain the methods you intend to use; it is also your study of other people's work in the area that you wish to investigate - and a description of how you learned from their research.

Literature Review - What has been done before in this area - related to a particular problem theme and your Research Question? This is all about preparing one's mind with all the topic area and research knowledge you will need.

Research Review - research into how the project investigation could be done and supported. At this stage student will already have an outline plan based on their approved specification but now the whole design must be thoroughly reviewed before actual work begins.

Knowledge of Alternatives – build a simple decision base which allows one to consider which methods could be used and how could they be used for this project.

Choices Made - which methods are to be used and rationally consider why they are good enough for the purpose.

9.2.3 Core Research

Here you execute the refined research design translated into a practical plan to obtain the collection of primary data and process it using acceptable methods into the intended project outcome.

9.2.4 Evaluation and Conclusions

This is the stage that looks at how one finishes off a project by a process of evaluation and the drawing of conclusions. In particular, it is needful to look at how one evaluates what was done and how it was done – that is, one needs to consider the project product (or outcome) and the project practice. For our purposes evaluating will be taken to mean reflecting on product and practice.

Many students confuse evaluation and conclusions but for a full consideration of the research work one must look at all project specific evaluation of results and outcomes as well as practices and then perform the more difficult step of drawing generalised conclusion about both product and practice.

Evaluation of Project Product – the specific project outcome or product is normally evaluated against objectives, other existing products, using defined criteria or some form of expert evaluation. Additionally, one needs to be aware of any constraints that might have an impact on the applicability of the outcome. However, typically one asks about the outcome (product): has it any value, who will use it, what will they use it for, will it get you your target effects that sort of thing.

Evaluation of Project Practice - evaluation of specific project practice is more difficult than evaluation of project outcome (product) and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking 'how well did I do it', 'was it successful' and 'should I on reflection have done it another way', 'did I make any mistakes', 'were there any surprises', "have I discovered any principles" and indeed did you learn anything. Additionally, one needs to be aware of any constraints involved, including time management that might have impacted on the use of best possible practices.

Conclusions – here we are trying to go beyond the obvious project findings and so we need to consider thoughtfully implications and meaning that arise out of an attempt to generalise about the topic based on your findings/outcome - that is you might have set your project in the Caribbean but do any of the findings have wider implications, are there general lessons to be learned, have you uncovered a principle or is there any sign of a best practice here that kind of thing.

9.3 Writing up your Project

The following sections describe elements that occur in almost all projects and which are generally important in constructing scholarly work. Do not be tempted to ignore these instructions – anyone who departs from the spirit of them may have their work returned for correction prior to formal marking.

9.3.1 Main Project Body Page Layout

The following shows how each page of a project report should look, note that each chapter starts on a new page and that it is NOT necessary to actually say Chapter 1, Chapter 2 and so on as it is the heading that is important. Do not use numbering to greater than three levels but you may use indented (but not bulleted ones) entries within a section at any level.

1. QUALITY CONTROL IN PROGRAM DEVELOPMENT

In this chapter the nature of quality will be discussed and its relation to physical measurable properties that might characterise quality.

1.1 INTRODUCTION

This project discusses a possible strategy for devising a program development methodology that goes some way to guaranteeing the qualities of the program code of delivered system. In particular it will concentrate on just two aspects - that of developing generic designs and code and how such designs could be assessed for quality and function. The strategy is based on the simple premise as endorsed by leading authors in the field such as Wilson and Bowers that categories of problem can be identified and formalised. It is the contention of this report that such a process would more or less automatically:

Reduce - the complexity of the design process itself.

Ensure - the quality of the final product by:

Giving managers more control over the product development cycle.

Giving users more idea of the kind of system they are likely to get and much more say in what the shape of the product will finally be.

Releasing programmers from the drudgery of having to design the same piece of code over and over again, thus enabling them to concentrate their efforts on new

1.2. Multiplicity of Design Factors

Every programmer has had the difficult experience of having to read and understand programs written by someone other than himself or herself. The sort of problem encountered may be aptly expressed in the following lines.

Everything has been thought of before, but the problem is to think of it again. (Goethe)

Many other authors, notably Frewin (1989) have discussed the notion of 'quality model ratios' and in essence this idea means that software systems have an implied model which can be accessed for

1.2.1 Multi-Tier Systems

In modern client sever systems

1.2.2 Interface Facades

In this case we look closely at the Internetetc

9.3.2 Plagiarism Checking

A software tool will check all your sources automatically and if plagiarism is identified it will be dealt with very seriously since the reputation of the whole course and of the University is at stake. You must remember, that copying, paraphrasing, summarising and similar techniques where the material is extracted from a source must be properly acknowledged. A simple rule is that if you use more than 6 consecutive words from a source it must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

9.3.3 Writing Abstracts and Identifying Keywords

The function of an abstract is to summarise your project, its context and its conclusions in order to give the reader an overview of the main project theme so that they can make an informed decision on whether they want to read the entire report. A good basic structure might be defined as follows but it will usually be limited to around 300 words.

What was the project about?

What did you actually do?

What were the conclusions/outcomes?

It is normal to add keywords or phrases after the abstract to act as specific pointers to content. There are no particular rules about how to construct these words or indeed how many there should be but typically there are 5 or 6 and to be useful they must be chosen with care in the sense that they might in themselves be regarded as a sort of abstract of ones work.

9.3.4 Standard Appendices

Project reports MUST include at least the following appendices:

Project specification and project Plan – it may be brought up to date from that submitted at the start

A glossary if this is appropriate

A full reference list of work that you cited

A bibliography (may be combined with your citation list)

Each Appendix should be introduced by a title where the number (12 in this case) should follow on from the numbering within the body of the report: **12. Appendix A – Project Specification.**

9.3.5 Typical Project Organisation

Below is a suggested organisation for your complete project.

Briefing Pages

Heading pages (examples follow later in the section)

Plagiarism declaration

Abstract for Report including keywords

Acknowledgements

Dedications

Content list (automatically generated) for all headings, tables and figures/graphs etc

Introduction:

Brief topic area outline and background to problem
Presenting Problem definition
Real World Target relevant to the problem
Speculation of problem causes/symptoms and possible solution routes
Personal Theory on the best solution route leading to a named outcome and actor
Research Question/Application Description
Scope and scale of work
Aim and Objectives

Literature Research (see Workbook 5 for recommendation for various project styles)
Detailed consideration of elements that help you focus on your topic area

Research Design

Research Method and its selection rationale in dealing with the research question/application
Process to collect Primary Data
Process definition to get from Primary Data to get an outcome

Application Testing (Engineering project only)

Design of Tests
Test Results and conclusions to be drawn from testing.
Implementation plans

Results Discussion and Presentation (study projects only)

Discussion and presentation of primary data
Generation of intended project outcome

Evaluation (this is specific to what you did)

Detailed evaluation of what was actually done – your practice
Detailed evaluation of your project product/outcome including objectives not met
Met/Not met objectives

Conclusions (here one tries to generalise what was done)

Main generalisations based on a consideration of both product and practice
It is also possible to examine the following minor conclusion elements but if this is all you produce the mark allocated will be very low.

- Usefulness of literature sources
- Future work/development
- Relevant aspect of the course used during the project period
- Changes one would make if project were repeated
- What you have learned
- Value-added features

References and bibliography (see workbook 5)**Content of Appendices**

The following items must be in a set of Appendices. These may be bound separately if the composite document becomes too large (more than 100 pages).

- Code listings
- Project Specification and project schedule
- Inclusions (copies of relevant documents such as policies, invoice layouts, diagrams etc)
- Questionnaires.
- Summary interview transcripts
- Details test plans
- Requirement catalogues
- Glossary
- Other

9.3.6 Project Types Sample Outline Contents

Broadly speaking there are two kinds of project: engineering where you build an application of some kind and study based where one would investigate in depth some idea. Here are some sample contents lists that show chapter or section headings for the different project styles. However, if it is obvious that these samples have just been copied into your project with minor changes then your work will be rejected. See Workbook 9 section 9.3.5 for further general details.

Sample Study Style Report Contents	Sample Engineering Report Contents
Title: Internet Marketing – A Users View	Title: BrokerBase – Insurance Sellers Information System
Chapter 1. Introduction to Internet Marketing	Chapter 1. Introduction to System
Introduction and contextualisation IT marketing problem theme Problem Theme, Target and Outcome Discussion and Exploration of Research Question Project aim and objectives	Introduction and Situation Overview Situation based Presenting Problem Application background and context Application overview Project aim and objectives
Chapter 2. Literature Review	Chapter 2. Literature Review and Application Scenario
Introduction to Internet Marketing Marketing Planning eCommerce Technologies and Tools Costs and Benefit Estimation Consumer Orientation and Market led operations IT supported Marketing and selling techniques Product, Price, Place, Promotion and Customer expectation IT supported Experiential marketing Security protocols and languages Auditing and secure payment systems	Outline of Insurance Brokerage practice Background Review of the Application Scenario Outline of Application Build Process and Tools
Chapter 3. Research Design	Chapter 3. Requirements Specification
Research Method Selection and Rationale Primary data collection process Data specification Data locations and expectations Collection Protocol Processing of Primary Data Collection Outline Results Project Outcome	Outline of the requirements (requirement catalogue into appendix) Research Plan for requirement gathering: functional, performance, technical and usability Outline Requirements catalogue Analysis and Evaluation of requirements
Chapter 4. Evaluation (Project Specific)	Chapter 4. System or Application Design
Evaluation of Project Outcome Evaluation of Research Methods and Protocols used	Principles used for this design Overall system design Build Process Overview Database design Component design Interface design including website
Chapter 5. Conclusions (Project Generalisations)	Chapter 5. System Implementation and Testing
Generalisations on the research Outcome Reflections on what was learned etc	Testing strategy Testing plans (detailed plan placed in appendices) Test results (detailed report placed in appendices) Application Implementation plans
	Chapter 6. Evaluation
	Evaluation of the application Evaluation of practice (methods and tools used)
	Chapter 7. Conclusions
	Generalisations based on the Application Reflections on what was learned Future work Etc
Notes	
1. Whatever the project styles the appendix must include: the project specification, glossaries, references lists, bibliographies. The appendices may be attached to the main report or they may be placed in a separate document.	
2. Remember these are just samples and you may well have different numbers of chapters and different heading and sub-headings	
Table 4. Sample Project Content Outlines	

9.4 Report Writing

In your research generally you will often have to write reports and of course you will have your final project report to write. Reports are a special form of writing and therefore you need to note that reports are:

- Written for defined purpose and targeted at a specific audience.
- Written systematically to present your of findings and outcome.
- Focused on what you have done.
- Information structured and formatted to lead reader quickly to main themes, findings and outcome

9.4.1 Structural Elements

It is important to structure all your work in a way that enhances its usefulness and utility. The following is a list of all the major structural elements, though there is no need to use all of them in every document you produce. The best advice is to choose a structure and then those elements that best suit the work in hand.

Structure	Description	Location
Title	A focused and short description of the document that summarises the deliverable element	Front page and above the contents list
Contents List	A short index based on the major chapters and/or sections	Before the main document begins but after the title page
Glossary	Used to list and describe special terms or abbreviations	Towards the end of the main document
Index	A detailed listing of all important words or phrases specifying location in main text	After the glossary if it exists otherwise after the main document
Appendix	For inclusion of explanatory notes, special documents or copies of originals	After the glossary but before the index
Footnotes	Notes at the bottom of pages and linked to pieces of text.	Immediately before the page footers
Headers	Standard text	Every page
Footers	Standard text	Every page
Keywords	Words or phases used to form a simple classification of your work	Near front of report
References	List of all reference material in an approved manner	Toward end of document
Table 5. Main Document Physical Structural Entities		

Organisation	Description
Chapters	Major elements in the development of the subject matter of the document
Sections	Minor elements in development of each chapter
Headings	Major Information Content indicators
Indents	Used to emphasise small but important points in the text
Bullets	Used to further emphasise an indented text
Tables	Used to represent important information concisely
Paragraph numbers	Used when it is necessary to reference all parts of a text
Page numbers	Used for indexing purposes
Diagrams	Used to show idea or data pictorially
Captions/Legends	Added to diagrams where necessary
Columns	Use when the subject material lends itself to such a view
Table 6. Main Document Structural Devices	

Presentation	Description	Examples
Font	Letter style and size	May be proportional or fixed point
Renditions	Printed form of font	Bold, underline, italic, reversed
Orientation	Page format	Portrait or landscape
Form	Delivery form	Paper, electronic
Table 7. Main Document Structural Properties		

9.4.2 Report Writing Stages

There are a number of stages to writing a report and they require you to be focused on what you are trying to say at the core of your report.

What are your trying to show – this really goes along with the underlying purpose of your research question – typically this will be about wanting: to inform, to explain, to evaluate, to prove, to advise, to recommend, to predict or to bring about changes.

Collect and sift material – it is important to jot down ideas relevant to your purpose. These jottings will help you form an action plan for gathering information from other documents, visits, interviews, observation, surveys etc.

Note – the exact location of information sources as you find them using Harvard APA format

Organise and structure the material - group your work into chapters, sections, sub sections, tables, appendices and so on and ensure their presentation order is logical.

Draft and edit/redraft – to get a good report you may well have to re-write it several times and this may include complete re-ordering. It is important that you need to be concise and use a formal language but it must be clear and concise. Use simple, straightforward words and sentence construction and make sure your spelling and grammar are faultless. Use clear headings and sub headings with bulleted indentations.

Thematic – make sure your work has clear themes that are easy to follow.

Plain English - do not try to be over-clever or fall into jargon.

Read Saunders chapter 13 pages 414 to 443. Don't skim on this or I might skim when I mark inferior work!

9.5 Project Submission Regulations

Successful project reports may be lodged in the University library, it is therefore important that reports follow a standard binding format as described below. Project reports that deviate from these regulations may be penalised and returned to you for correction and in extreme cases, failed.

Submission - two full bound A4 portrait orientation copies of your report must be submitted by the due dates. The report may NOT be submitted electronically – the copies must be sent by courier to reach us by the defined dates. However, you must also submit soft copies on either floppy disc or CD/DVD.

Presentation and Submission Checklist – your project report must be submitted using the correct form shown in Workbook 10. The form must be bound into your project.

Report Length - the maximum permitted report length is 15,000 words, which usually translates into around 50 to 100 pages (excluding appendices). If your report is likely to be significantly longer than this, consult your supervisor as to what to include and what to exclude. You are warned that should you exceed the permitted maximum length the University may return your work unmarked.

Binding - the project and any separate appendices should be securely bound using tape or book binding - if that is not available then plastic ring binding may be used. No other form of binding is permitted. Binding covers should be a card of weight of 140 gsm and the normal colour is to be RED but any other colour may be used in case of sourcing difficulties

Front Covers Format - the front cover appropriately spaced vertically should conform to the pattern shown below using 24-point Arial Narrow with centred text and bold as shown. Do not include the square brackets when you complete these formats as they are just placeholders

University of Portsmouth

School of Computing

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[Student No.]

Supervisor: [Name of supervisor]

Project unit Code [Project unit code]
[Month and Year, e.g. September 2004]

Title Page - the first project contents page, appropriately space vertically must contain the following information in the order shown below using 12 point Arial Narrow/Time Roman type throughout. Do not include the square brackets when you complete these formats as they are just placeholders.

University of Portsmouth

School of Computing

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[Student No.]

Supervisor: [*Name of supervisor*]

Project unit: [*Project unit code*]
[Month and Year, e.g. September 2001]

Abstract - [The abstract of the project should be between 150 and 300 words in length and constructed to say what the project was about, what you did and what were the conclusions]

Keyword List - [List of appropriate key words]

Acknowledgements Page - it is common practice to add a page listing those you wish to thank for their help. Acknowledgements should **only** be given to people who helped you directly with your work but were not involved in it. For example, if a colleague supplied you with a statistical analysis they should be acknowledged. However, it is not usual, necessary or desirable to acknowledge your parents, your wife or your friends.

Submission Form and Plagiarism Declaration

You must add the following two pages which require a signature. In practice one adds the signature to the final bound copies.

Declaration of presentation Standards

Include at this point a completed copy of the project submission checklist shown in workbook 10. Be warned, that if you tick this page and the relevant element is not found to be present, the work will be returned to you unmarked for correction.

Plagiarism Declaration

I confirm that the enclosed written work (including application code) is entirely my own except where explicitly stated otherwise. I declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions. I understand that wherever 6 or more consecutive words are extracted from a source they must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

Signed _____ Date _____

Contents list, Table List and Diagram List

Include as appropriate

9.6 General Grade Criteria

Workbook 14 gives general guidance as to how projects will be assessed and also contains a table of the criteria used, although the emphasis given to various aspects may vary depending upon the nature of the work and should be explained to students in assessment specific criteria.

9.7 Project Examination Board Reflections

This is a discussion based on observations made on the marking forms and in the Examination Board regarding the quality of the submitted document as final Master's projects/dissertations. Most of these faults are due to shallow and sometimes very shallow thinking on the part of the project student and that is unacceptable at Master's level. The following points are to help both supervisors and students avoid known pitfalls and so produce a project document to a high standard.

9.7.1 Project Introduction – Study Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem definition – common deficiencies were no discussion or poor discussion of what problem was being addressed by the project. Without such a discussion it is almost impossible for a reader to get any grasp of what the project is about. In projects we want to see just ONE major problem theme not several so it often requires clear thinking to set it at the right level. (See workbook 6 section 6.2 and 6.11)

Target, Outcome and Actor – there is often considerable confusion over these ideas. The target is about what might happen in the real world based on the project outcome but often students cannot distinguish what the project will generate and what might be done with that project outcome by situation actors. As a simple example, students might say that the project outcome is "improved accuracy in data entry" when what they mean one supposes is that in their project they will design (say) a new training programme that will be used to get the real world target of improved accuracy. (See workbook 6 section 6.3, 6.4 and 6.5)

Speculation and Personal Theory – students are encouraged to speculate about problem causes and solution routes to arrive at a personal theory about the problem theme and how it might be resolved leading to a suggestion of an expected project outcome. A reader expects to see some indication as to what form the project outcome will take and in addition some discussion of the form to at least show that it is likely to go some way to resolving the stated problem theme and can indeed be used by the named situation actors. Unfortunately, the outcome was often missing or confused with the target and even when the Research Design was consulted a typical reader could still not see what the project outcome was supposed to be. Here we want to see ONE major form outcome for each project. (See workbook 6 section 6.6).

Research Question – often missing, badly worded, many of the 6 required features missing or multiple questions offered (sometimes all in one sentence). One common mistake was to ask a question in the form (or some equivalent) of "is it possible...." - the point is that in such questions the answer is almost always that it is possible so the research effort becomes pointless. (See workbook 6 section 6.8)

9.7.2 Project Introduction – Engineering Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem Theme - there was either no discussion or poor discussion of what problem theme the application being built was supposed to resolve. When this happens it is almost impossible for a reader to get any grasp of what the project is really about. (See workbook 6 section 6.2 and 6.11)

Functional Description - many students could not provide a short functional description of the application they were going to build. The most common thing for students to do instead was to provide an overview of the application architecture. This is hopeless as architecturally almost all Engineering projects are the same in that they typically have a database and a webpage for example. This implies that students cannot or do not want to make a distinction between how an application is built and what its purpose is.

9.7.3 Aim and Objectives

In many cases these elements were missing altogether. In other cases one could barely link the aim to the Research Question or application description. However, of most concern was an apparent inability in many students to write a coherent and reasonable set of objectives. Not to be able to write an aim and more particularly objective is representative of a gross student weakness and it should never occur in Master's level work.

Aim - usually composed in a reasonable way but there does seem to be an inclination in some students to cram everything into the aim as if they are some kind of superman. The recommendation is to have just ONE clear activity mentioned in the aim and that should be accompanied by a just one clear outcome for the aim. (See workbook 6 section 6.13, 6.13.1)

Number of Objectives - often there were far too many to be in any way practical for one student in the time available and often this was because they were all expressed at different levels of project resolution or confused with minor project tasks. (See workbook 6 section 6.13 and 6.13.2)

No Visible Outcome - there were many, many cases where the objectives had no visible outcome. Far too often we got phrases such as: "To understand...." or "To analyse...." without any object to the sentence so there was no outcome that was visible. Without a named outcome there is no way that the objectives can be seen to have been completed. (See workbook 6 section 6.13 and 6.13.2)

Not Project Bounded - there were many students who cited operational objectives as outcomes. For example it was common to see lines such as "To improve the workflow in the invoicing section". Here is a case where such an outcome cannot be written into a document or be in practical terms viewed and so cannot be used in a project. Typically, unbounded objectives refer to something that might happen based on the project outcome after the actual project has been completed (See workbook 6 section 6.13 and 6.13.2)

Objectives as Requirements - very commonly but still rather worryingly, many students, on Engineering projects, seem to think that objectives are the same as application requirements. (See workbook 6 section 6.13 and 6.13.2)

Objectives as Benefits - less commonly but still rather worryingly, many students, on Engineering and study projects, seem to think that objectives are the same as benefits. For example, in a study project on CRM systems what one often finds in place of project objectives is a list of benefits of implementing CRM. Similarly, for Engineering projects we see objectives written as a set of benefits of using the application being used later on in the real world. (See workbook 6 section 6.13 and 6.13.2)

9.7.4 Literature Review

In research the literature review is regarded as being essentially preparation of the mind. It follows, that to be serious about this step one has to be evaluatory and reflective as you read and write. Ideally one needs a strong theme which is used to weave an expository and exploratory discourse that unites and builds one's understanding and ideas with what has been written by other authors on your core topic area.

For projects a full literature review is only needed in the case of a study project. For Engineering all that is required is a thorough overview of the application area. So for example, if an application where about Insurance brokerage then all that is required is a description of what brokerage is but only to the level necessary to understand the requirements. See workbook 5 but section 5.2, 5.6, 5.7 and 5.8 should be studied with care.

Structure - many reviews were poorly structured and one often felt that the students had just written down the material as it occurred to them without any thought as to a wider readership.

Theme - often there was no detectable theme connecting the various sections of the narrative and a reader would therefore be forced to guess at how all the various elements were connected.

Value Added - the most common flaw was to see a review that was entirely or almost entirely made up of quotations, paraphrases or summaries so that the 'hand' of the student was not detectable anywhere in the work. Such work is not evaluatory and gives no indication whatever that the student has learned anything of value or indeed anything at all. It is often the case that one feels the student has no notion of the literature being a driver that may mean they have to accept new knowledge, gain further experience, modify existing knowledge or even abandon what they thought was sacrosanct and sadly no belief that their own views and experiences are also important.

Citation Style - two things are evident here. Firstly, one finds that too often citations are limited to the Literature Review. Secondly, the actual style used is very poor and commonly we see the form (Burk, 1992 p45) placed at the end of a sentence or paragraph - this is not acceptable and can only mean the whole paragraph has been paraphrased. The ONLY correct use of this bracketed style is in a passing reference to a text. (See workbook 8)

Worthless Quotes/Paraphrases - it is unfortunately only too common to see an appeal to some text or other for information that tells you either common knowledge or makes an obvious observation and so the citation is worthless and is representative of weak scholarship and laziness where a student is just trying to add a citation because he knows that such things are desirable. For example, quoting an author who says that "Object Orientation is now routinely used in software construction" is representative of common knowledge or quoting an authors who "says change is inevitable" is something that one might regard as obvious.

9.7.5 Research Design

These were often far from satisfactory and often read like a joke delivered without the punch line. The students are taught that essentially there are two phases. The first phase is the process used to get primary data items that are formed into a set. Once the collection phase is completed we move on to the second phase of processing where the set of primary data items is processed to get an answer in the form of expected project outcome. Particular points are:

Research Phases - In many cases students were unable to distinguish the processing needed to get a set of primary data and processing of the set to get an outcome. It is quite common to see these two phases ignored or become completely muddled leading to a poor research outcome because the student loses his/her focus and often appear to have no clear idea what they are doing. The phases are:

Data Definition and Collection - a process or processes used to define and create a primary data set. It typically has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the data and present the data.

Data Processing - a process or processes used to manipulate the primary data set to get the project outcome.

No Outcome - often it seemed as if the student had no idea what project outcome to expect so when one looked at the processing there was no sense that the primary data was being used in any way to generate the required project outcome. See workbook 6 section 6.4

No Situation Actors – this occurs when we have an outcome but no idea who (person or persons) will use it to generate the target effects. See Workbook 6 section 6.5

Primary Data - many students seem to have only a vague notion of what primary data is and will often, very often, confuse or think that primary data is the same as the method of collection. This confusion is often evident with some students thinking that only questionnaire data could possibly be primary data.

Primary Data Definition - Primary Data is new data in the sense that it will not exist as a set until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data set is representative of some aspect of the area under investigation and can be processed to get a defined project outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

For example, one student took the definition and then read through an accounting system manual for his company and extracted all the functions and claimed that was primary data because he was going to use it to define what an accounts package should have by way of functionality but seemed unable to see that the manual had effectively done that already. (See workbook 6 section 6.7)

Research Method Justification - often students could not distinguish between Research Method and Data Collection Protocols. Research Methods are frameworks such as Case Study, Experiment, Action Research and so on. Collection protocols are based on: interview, questionnaire, observation, role playing, seminars, focus groups and so on. The sorts of justifications used are of the form "I have chosen case study because Saunders (2005, p92) said case studies are good..." - this is hopeless and implies no real thought. Justification must be built from a sound understanding of a particular Research Question, its expected form of answer (project outcome) and the Primary Data needs and at least an overview of which method is likely to be best in a given situation. (See Workbook 7)

Practicality - many plans were over-complicated with students trying to use multiple methods and then ending up with masses of data they had no idea what to do with. There is only limited time and so students should be encouraged to focus on just one Research Method although of course several collection protocols may be involved.

Data Collections - in many cases all an examiner was able to see were presented results but often one simply could not tell if any primary data set was involved and the results just seemed to appear 'out of the air'. The marking guide is quite specific and projects must be clear about both processed data and raw primary data sets. Without this we cannot feel confident that students have done any actual research. Typically, the primary data set is placed in an appendix and might be in the form of a summary table of questionnaires results or summarised transcripts. Correspondingly, the processed primary data set is expressed as charts, graphs, tables, reports and so on in the body of the project report.

Processing - this is one of the most disappointing elements. Processing is all about transforming your primary data set into the project outcome. Far too often all we see is the processing of individual primary data items with no attempt or very weak attempts to really supply an answer to the Research Question in the form that was specified.

Location - there were quite a few projects where it was more or less impossible to see where the primary data came from and often this was accompanied by a very ordinary set of results that could have been written by almost anybody with a superficial knowledge of the subject area.

9.7.6 Research Results Processing

There were some very good examples but often this section was very routine and very disappointing.

Repeating - it was very common to see a chart for example, displayed and then underneath the student simply repeated the data that was in the chart in words. Such a practice is worthless. What any data related narrative is supposed to do is to tell the reader what the data means and what implication it might have - that is we expect to see some analysis and evaluation of the data in terms of the Research Question.

Focus - the focus of processing the primary data is to create a kind of transformation that generates from the primary data set the expected project outcome - unfortunately, this aspect was often absent. Typically in a survey for instance we have page after page of charts analysing individual data items but no attempt to sum it all up and reach a conclusion based around the Research Question.

9.7.7 Evaluation and Conclusions

These sections in a lot of student work are indistinguishable. The reason there are two sections with marks attached is because:

Evaluation - here one focuses specifically on the project outcome and research methods - that is we evaluate our product (outcome) and the methods used in its generation. Notice here this is NOT about generating the outcome that would have been done in the primary data processing section

Conclusions - here the attempt is made to say what it all means - that is trying to generalize the findings. So for example, suppose the outcome is about the use of Agent technology in eCommerce web sites then in conclusions one might try to say what a particular project outcome means for any eCommerce site or in fact any website. In a similar kind of way, if a particular application had been built we might try to say whether it might be applicable in other situations or whether some features of the design can be transferred to all applications of that type.

9.7.8 Ignorance of Project Marking Criteria

Many students show an almost complete disregard for the way a project is marked and so often automatically lose marks. Students must therefore carefully study the marking forms so that they know what components are regarded as essential to any project and therefore carry marks. (See workbook 11 or 12 as appropriate)

10. WORKBOOK 10 – FORM: PROJECT SUBMISSION

This form **must** be completed and included in your project submission. If you are unable to tick every box then your work is not ready for submission.

Project Word Count	Exclude appendices. If maximum is exceeded marks may be lost or the project rejected
	The report length is within the stated guidelines (15,000 words maximum excluding appendices)
	I have included all making elements indicated in workbook 11 Or 12 as appropriate and noted the marking guidance notes
	I have studied the guidance notes on common project faults found in section 9.6
	I have prepared two bound copies of all my project work including any separate appendices
	I understand that I may use one or both sides of the paper when printing the report.
	I have included a full contents list, table list and diagram list all numbered consistently
	I have used good quality A4 paper, normally in portrait orientation with a weight between of 80 and 100gsm.
	I have made sure that the pages are in the right order and none are missing
	I have used MS word .doc format
	I have formatted the front cover and title page as required and added the necessary plagiarism declaration.
	All my text is single line spaced at 6 lines per inch/25.4 mm.
	All my main text, including headings is in 12-point font (Arial Narrow is recommended)
	All my text in tables and diagrams is 10-point font (Arial Narrow is recommended)
	All main text is right and left justified
	No headings at whatever level are indented
	Headings are NOT followed by a blank line
	Headings are in the same font and size as the main text but are shown in bold type
	No numbered headings are orphaned (that is all heading must be followed by some text not immediately by another heading)
	I have used a single blank line to separate paragraphs
	All chapters and appendices are numbered sequentially (1, 2, 3,...)
	All subsections are numbered (2.1, 2.2,...) and none of my sections numbers exceed three levels (1.2.1, 1.2.3 ...)
	All my margins: (top, bottom, left and right) are 20mm
	All pages have footers in 10-pt Arial Narrow in form: Page 12 of 97 - J.Letto Student No. 567543 Submission Date: 12.10.07
	I have cited other people's work properly using the Harvard APA format
	I have included all citations in my list of references
	My abstract accurately summarises all of the report, not just parts of it
	All my chapters and appendices start on a new page
	I have included appendices, where appropriate, covering: project specification, Project Plan, Requirements document(s), design document, screen shots, source code, user documentation, test results, evaluation results, questionnaires, etc.
	My supervisor has read each chapter as the work progressed.
	My supervisor has read the whole report
	I understand that indented sentences can be used where appropriate but bullets are not recommended (see 9.3.1)
	I understand that page headers are not required
	I understand that each of my chapters should start with an introductory section that explains what the chapter is about
	I understand that each of my chapters should end with a summary and a helpful link to the next chapter
	I have fixed a copy in .doc format of the project document and any appendices on floppy/CD/DVD to my project submission
	All my primary data (including requirements data) is original to this study and collected by me for this specific project purpose
	My primary data collection is available in the project document or appendix (if necessary in edited or summarised form)
	Engineering Projects only - I have included an executable file of my application on an attached floppy/CD/DVD
	Engineering Projects only - Application Operating instruction are on the attached floppy/CD/DVD as well as in the appendix
	Engineering Projects only – In my application I have not used illegal copies of any software or included any software where there is an expiry date which may render the application inoperable in the future.
	Engineering Projects only - I understand that the copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If, and only if, this is not possible then I have included in my project a supervisor signed set of screen shots in the appendix confirming that he/she has viewed the application in action.
Signature of Student.	Date.

11. WORKBOOK 11 – FORM: STUDY PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

STUDY STYLE		Postgraduate Project Marking Form						STUDY STYLE	
Name of Student							HEMIS No.		
Brief Project Title							Total Mark	%	
Recommendation	If the mark awarded is a fail circle you opinion						Re-Work	New Topic	
Name: Supervisor									
Name: Marker									
Marker Status	Supervisor		Moderator		3 rd Marker		Re-Marker		
Project Unit	PJ.NCC								
Plagiarism	N	Y	Is PLAGIARISM or another unfair act is suspected						
External Examiner	N	Y	Refer to the External Examiner (if “Y” add comment in section G)						
Content	Y	N	Can you confirm that this project fulfils the criteria for the Unit

Section E – Qualitative Assessment matrix based on University Grade Criteria									
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words			
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless			
3.	Report structure	very poor	poor	satisfactory	good	excellent			
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report			
5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours			
6.	Project idea	trivial	easy	modest	challenging	Difficult			

7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Primary data collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Data processing	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
14.	Main project outcome	Worthless	obvious	useful	original	exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Study Format Marking Form Guidance notes These notes must be read in conjunction with the grade criteria and associated notes found in Workbook 14.
Section A - Marks for Planning and Preparation
1. Project specification, including project plan
Reference: Workbook 3 section 3.3 for general notes and section 3.5.2 for an example specification
Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.
2. Review of the topic area literature
Reference: Workbook 5 section 5.2 and 5.6 in particular, Workbook 8 and Workbook 9 section 9.6.4
Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers and generally be focused on the central project topic. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.
Section B - Marks for Project Introduction
3. Presenting problem and its exploration including the Research Question
Reference: Workbook 3 section 3.3 and 3.5.1, Workbook 6 sections 6.2, 6.6 and 6.7 and Workbook 9 section 9.6.1
All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Research Question with a defined form of answer (project outcome). It is very common to see an expression of a problem as "my problem is to find a solution to..." or expressed in such a way that it is in effect a solution and such expressions are indicative of students who do not know what the problem is but nevertheless know what the solution is. Similarly, students who list multiple problems, have no Research Question (or a very poor one) and do not discuss the form of outcome expected are embarking upon projects where there is no clear focus and these typically fragment when it comes to the core research and one most often cannot find any clear project outcome later in the work. It is also useful at this stage if there is some indication of the Basic Activity for Generating Data (BAGeD) so that one can feel sure that the student is aware of what primary data they need in order to generate the intended outcome.
4. Discussion of the project's scope, scale, aim and objectives
Reference: Workbook 3 section 3.5.2 (example), Workbook 6 section 6.1 and Workbook 9 section 9.6.3.
Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition, expected form of outcome and Research Question all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.
Section C - Marks for Project Primary Data Research and Outcome Generation
5. Selection and justification of Research Method
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Markers should look for a rational and thoughtful choice of Research Method focused on resolving the stated problem theme. In practice this implies a consideration of primary data needs, location of primary data and the collection protocols that might be used. Markers should guard against rationales that amount to saying that some text book or other said method X or Y was good for certain kinds of scenario – that is copies of generalisations about Research Methods found in books do not amount to a rational for a specific research situation. Furthermore, markers need to feel confident that the student understands the distinction between a Research Method and the collection protocols used within them.
6. Primary data collection plan including data specification
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
This is a crucial stage in a research based project and markers must be confident that the plan is practical. A marker must look for a clear core activity represented by a statement about of BAGeD and that core activity should be surrounded by whatever other processes are needed to ensure reliable collection of the primary data. The whole primary data collection plan has four steps which must be visible in the project document: data definition, data location, data collection and how the whole collection of primary data is to be presented. Markers should also take care that the formation of a collection of primary data is not confused with the processing of it to get the stated project outcome.

7. Primary data processing plan and presentation of the expected outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for clear evidence that the student has taken the collection of primary data they obtained earlier in the project and now process that whole collection to get to a clear presentation of the project outcome. It is therefore important that markers can see what processes were applied to the collection of primary data to get the outcome – without this process visibility there is no evidence as to how the project outcome was actually obtained. Markers should be wary of processing plans that say such things as “I will look at the data” or “I will analyze the data” or “I will use SPSS” as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same data collection they could apply the same processes and get the same or at least a very similar outcome.
Markers should also be aware that very often students will often process individual data items – such as might be found on a questionnaire, but never get to a point where the stated project outcome is derived from the collection of data.
8. Presentation and discussion of the collection of Primary Data
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for visible signs of the collected primary data. The primary data collection is most often presented in tabular form in the appendix and might be displayed as graphs, charts, tables or diagrams in the main project document.
9. Expression and description of main project outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
The intended project outcome must be clearly visible – for example if the intended outcome is a model then that must be clearly shown in some acceptable form and be based on the processing plan outline in section 7. Markers must therefore take great care that the presentation of primary data and the processing of individual data items in the collection are not offered as a substitute for the student generating the intended project outcome.
Section D - Marks for Project Evaluation and Conclusions
10. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project outcome so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution (project outcome) or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project outcome. The section is not intended for vague thoughts about the topic but a considered evaluation of the project outcome when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
11. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate here. This section is important as this is where one expects to find some information on what the student has learned about the way they work and the tools they used. It is unfortunately often the case that students have very little idea about what they did apart from stating vague activities such as “look at”, “analyze” or “use SPSS” so without anything concrete to evaluate they resort to the routine and say “the survey process went very well” or “my case studies generated useful data” or else they simply ignore this form of evaluation altogether. Evaluation of project practice is difficult and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking ‘how did I do it’, ‘was it successful’ and ‘could I or should I on reflection have done it another way’. Additionally, one needs to be aware of any constraints involved, including time management and particular skills that might have impacted on the use of best possible practices.
12. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a project outcome was based on case studies and the outcome was a review of IT outsourcing in Hong Kong then here we might expect to see the student consider the outcome he obtained which refers to Hong Kong and then consider and discuss whether that outcome has wide applicability, for example, to China, South East Asia or even the world as part of a Global economy or is it just specific to that local situation. Essentially, one is asking what do the outcome ‘mean’ when set in a wider setting. It follows that the focus of awarding marks here is for project generalisations.
It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such as future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

12. WORKBOOK 12 – FORM: ENGINEERING PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

ENGINEERING STYLE		Postgraduate Project Marking Form				ENGINEERING STYLE

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Engineering Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.1 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the application/product area and its client/business setting

Reference: Workbook 5 section 5.2 and 5.6, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers. In Engineering projects the expectation is that the review will focus on the application area and be in enough detail to at least understand and gather the requirements. It is permitted to include technical material if they have a special or unusual significance to the application area but in so doing students must be aware that the routine inclusion of what at this level might be regarded as common knowledge in computing/IT will not attract any marks. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and Outline Proposal

Reference: Workbook 3 section 3.3 and 3.5.1 Workbook 6.2 and 6.5, Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Application Outline expressed as a functional description. It is very common to see an expression of a problem as "my problem is to find a solution to..." and this is indicative of students who do not know what the problem is but nevertheless know what the solution is. Students who list multiple problems, have no functional description (or a very poor one) are indicative of projects where there is no clear focus and these typically fragment when it comes to requirements gathering and often end in a very trivial application. Markers should be aware that students may avoid giving a functional description and instead offer a generic architectural one and this must be penalised as the student clearly does not know what function the application supplies

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.1 (example), Workbook 6 section 6.11, 6.9 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition and Application Outline all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Detailed requirements collection plan based on proposal

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful consideration of the Requirement Gathering process focused on obtaining sufficient information to build the intended application and resolve the stated problem theme. In practice this implies a consideration of application functions, location of requirements data and the collection protocols that might be used. Normally in research one would expect a rationale for the choice of Research Method but for Engineering projects it is taken for granted that the method is requirements gathering. Instead one should look for a clear focus on constructing a feasible and comprehensive requirements document based on the application outline. Furthermore, markers need to feel confident that the student understands the distinction between Requirement Gathering as a Research Method and the collection protocols used within it.

6. Analysis of requirements: functional, performance, technical and usability

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers must look for a clear Application Proposal and a requirements catalogue. Here one needs to see a discussion of the requirements to ensure they are credible (realistic), comprehensive, complete and stakeholders have been considered. One might also usefully consider the approach that was taken to gain them and whether they are of the form of strategic, tactical or operational.

7. Presentation, analysis and discussion of the design
Reference: Workbook 9 sections 9.6.5 and 9.6.6 and Workbook 7 section 7.9
Marks are awarded here for clear evidence that the student has taken the requirements obtained earlier in the project and processed them to get a suitable design. Therefore, markers must be able to see a clear link from requirements to design and where necessary observe how the requirements were processed. Markers should be wary of processing plans that say such things as "I will look at the requirements" or "I will analyze the requirements" as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same requirements they could apply the same processes and get the same or at least a very similar outcome.
8. Discussion of build process and design implementation
Reference: Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for a rational discussion as to what architecture, components, languages and tools and so on are needed to best implement the design. This discussion may also imply the various situation constraints have to be considered as well.
9. Application testing process and results
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers must look for evidences of a testing plan and a consideration of test results. Typically the plan and results are placed in the main project document in outline form with the details in an appendix. Often students will just discuss white or black box testing or regression testing or something similar but without any actual test plans or results – in such cases marks should not be awarded as these materials is considered common knowledge at this level – however brief references to it are permitted.
10. Implementation plans
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers should look for a comprehensive implementation plan – it need not be extensive or in minute detail but it should cover installation, user training, data conversion/loading, change over, user acceptance and hand-over.
11. Attributes of the project artefact (e.g. quality, reliability, etc)
Reference: none
The intended project application must be clearly visible and available to run directly from a disc or DVD. Markers are to award marks based on their perception of the general quality of the application if they were to put themselves in the place of a user. Assessment may then consider colour scheme, ease of use, operating instructions, presentation (does it look as if its finished), speed, etc.
Section D - Marks for Project Evaluation and Conclusions
12. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project application so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project application. The section is not intended for vague thoughts about the situation or application but a considered evaluation of the project application when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
13. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate. This is where one expects to find some information on what the student has learned, the way they work and the tools they used. It is often the case that students have very little idea what they did apart from being able to state vague activities such "look at" or "analyze" so without anything concrete to evaluate they resort to the routine and say "the survey process went very well" or "the UML modelling was straightforward" or else they simply ignore this form of evaluation. Evaluation of project practice is difficult because the student must ask searching questions related to process success and the notion of good and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way' or "what were my constraints".
14. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a an application was for eCommerce selling shoes it might be possible to ask what aspect of that application could be re-used to sell other product. It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

13. WORKBOOK 13 – FORM: PROJECT MARKING RECONCILIATION

The form shown below is included for reference only so that you can see how your project will be marked.

Project Mark Reconciliation Form		Final Agreed Mark (%)	
Name of Student			
Brief Project Title			
Name: Supervisor			
Name: Second Marker			
Name: 3rd Marker			
<p>Cause – in this box, describe, for each applicable section, why the marking disagreement occurred.</p> <p>Rationale – in this box, If a mark can be agreed, explain the rationale used to reach agreement. Please note that it is only necessary to agree the total mark for each section not individual category marks.</p> <p>Irreconcilable - If you cannot agree a mark leave rationale blank and it will be filled in by a third marker who will place a tick in the small square box.</p>			
Section A - Marks for Planning and Preparation		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			
Section B - Marks for Project Introduction		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			
Section C - Marks for Project Primary Research and Outcome Generation		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			
Section D - Marks for Project Evaluation and Conclusions		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			

14. WORKBOOK 14 – SUPERVISION AND MARKING GENERAL GUIDANCE NOTES

1. **Presented Work** - Marker's are reminded that any marks awarded must be solely based on the assessment of work presented within the mark categories listed on the mark forms. It is not permitted to award marks for "hard worker" or "tried very hard" or "was a good student" or any similar observation as there are no relevant mark categories and this kind of criteria is almost impossible to evidence.

When an Engineering artefact is presented it should be viewed in action to ascertain the mark for "Attributes of the Project Artefact". The copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If this is not the case then markers must assume that there is no evidence for the application and set the mark accordingly.

2. **Word Count** – on the project submission form there is a space for a word count (excluding appendices) and if this is exceeded then it is indicative of a deliberate attempt to go beyond recommendations and you may therefore find that it leads to laboured descriptions or inclusion of irrelevant material in the project document and you should therefore mark accordingly.
3. **Structure** – mark categories do not necessarily represent chapters in a project document and so Marker's need to be aware that a particular project may be structured in a way that does not correspond to the sequence presented on the mark forms (though it is recommended to do this when possible). However, all the elements on the marking form must be visible in the work presented.

Although it is recommended that the mark form sequences be followed in the project document that does not mean that there has to be a chapter for each mark category. Students, therefore, should be encouraged to merge sections in order to produce a concise document. For example, it is perfectly possible and reasonable to merge the two evaluation sections and conclusions into one chapter as long as the relevant mark elements are still visible.

4. **Appropriateness** - any work presented must be within the prescribed subject area for the course. If a marker suspects that this is not the case then they should consult with the relevant course leader for clarification. In such accepted cases markers must regard the primary data and its processing as not being appropriate and mark with that in mind.
5. **Evidence** - the project report or appendix must contain sufficient evidence that the core project research work has been done (not the literature review). That is, in the case of study project a marker must be able to see the primary data collection appropriately presented (usually in an appendix). In the case of Engineering projects it must be possible to see a suitable requirement document or catalogue (possibly in the appendix). Once the primary data is visible then it must also be possible to see how that data was transformed into the intended project outcome.
6. **Literature Support** - when marking Literature Reviews their content must be seen to be focused on the topic area and address clearly the associated problem theme without any irrelevant material with the intention of offering a concise discourse that is focused, relevant, authored, measured, evaluatory and expressed as a dialogue. (see section 5.1)
7. **Grade tables** - markers must be aware of the criteria associated with awarding a given overall mark as they may be required to justify it to the UAB in terms of the criteria stated in the table shown below.
8. **Process** – when marking it is important that the process used to get an outcome by the student is visible in the project document. In practice this means that it is possible to perform the following trace: presenting problem, discussion of how problem might be resolved, suggested form of project outcome, research design and execution, generation of stated outcome, evaluation and conclusions – viz:

Engineering – typically, the process starts with a business related or technical problem theme leading to a research plan for the collection and discussion of requirements and their transformation into a suitable design and associated architecture. From this there should follow a build, implement and testing process with the whole project completed with suitable project specific evaluations and conclusions containing generalisations.

Study – typically, the process starts with a business or strategic IT related problem theme leading to a research plan for the collection and discussion of primary data and its transformation into an outcome that would resolve or go some way to resolving the stated problem theme. The whole

project is then completed with suitable project specific evaluations and conclusions containing generalisations.

Marks	Master's Level Grade Criteria
70 – 100	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Excellent work - able to express an original reasoned argument in a lucid manner by reviewing & critiquing a wide range of material. Original, critical thinking based on outstanding insight, knowledge & understanding of material. Material contributes to current understanding & is of potentially publishable quality in terms of presentation and content ▪ Wide reaching research showing breadth & depth of sources
60 – 69	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Clear, balanced coherent critical & rigorous analysis of the subject matter. Detailed understanding of knowledge & theory expressed with clarity ▪ Extensive use of relevant & current literature to view topic in perspective, analyse context & develop new explanations and theories
50 – 59	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Detailed review and grasp of pertinent issues & a critical contextual overview of the literature. Thorough knowledge of theory and methods & uses this to underpin arguments and conclusions ▪ Confidence in understanding and using literature
40 – 49	<ul style="list-style-type: none"> ▪ Demonstrates grasp of key concepts & an ability to develop & support an argument in a predominately descriptive way with valid conclusions draw from the research ▪ Familiarity with key literature which is cited and presented according to convention ▪ Logical & clear structure, well-organised with good use of language and supporting material
0 – 39	<p>FAIL – Some knowledge of relevant concepts & literature but significant gaps in understanding and/or knowledge. Little attempt at evaluation, conclusions vague, ambiguous & not based on researched material. Limited or inappropriate research. Deficits in length, structure, presentation &/or prose.</p>

This form may be used by you to feedback to the University your experiences in the courses. It is normally sent to your tutor at the end of the course.

Research Methods Workbook - Release 3.3b Dated April 2007© Page 85 of 87

16. WORKBOOK 16 – USEFUL BAGeD WORDS

These words and their definition may be used to formulate your BAGeD idea is a research design

Account for - Explain and clarify something by giving reasons

Analyse - Resolve something into its component part, or examine critically and minutely.

Appraise - This is best thought of as something like forming an opinion about something. It might be quite simple such as forming an opinion as to whether something is good or bad but more often that not it's about forming an opinion about something after assessment or evaluation with regard to what can be done - so we might appraise whether a process for example should be left unchanged, modified or made redundant.

Assess - Determine the value of something. Similar to evaluation but it is often useful to think of evaluation as a qualitative process and assessment as a quantitative one.

Catalogue - This means to create an ordered collection of some sort where there is a logical order and the essence of the task is to enumerate and describe

Collect - This is very simple as all one does is to identify the data and literally collect it as you see it. So if I were looking for SPAM instances then as soon as I find one I just file the whole SPAM email away for later processing.

Compare - Look for similarities between one or more things.

Compile – similar to list but here the implications is you search many sources but in doing so having to make decisions in the process

Contrast - Look for differences between one or more things.

Criticise - Make a judgement, backed by a discussion of the evidence or reasoning involved, about the merits of theories, opinions, .

Define - State the exact meaning you are attaching to a word, phrase, idea, process etc

Describe - This may be used freely to describe in detail situations, events, opinions, feelings and so on.

Differentiate - Look for elements that would clearly differentiate between two or more things

Discuss - Explain something by giving two sides of the argument

Evaluate - In some cases one might want to look at events or people or processes in order to form an evaluation and that collection of (usually) small evaluations form our primary data.

Examine - Look carefully at the details of an argument, theory, or plan etc

Explain - this is about saying why something is. So one can describe an event but also explain why it occurred

Explore - You can use this word but we are always exploring so it must be used with care. Typically, in these cases one starts with a model of some kind and uses that to inform the exploration process. For example, we might have a theoretical process map and we use it to explore various working processes to see if we can find flaws or weaknesses and then those descriptions of flaws or weaknesses become our primary data.

Illustrate - Here one is trying to find a way to express in a very pointed way some situation or thing. So one might identify an instance of SPAM and then illustrate why it might be harmful so adding poignancy to the example you have extracted. Mostly, it is best to think of illustration as a way of giving an example but in that example you want to make just one clear point.

Interpret - The essence here is that one is typically observing something to describe it but also to find some meaning in what is being done. This is often used when looking at social groups or situations where it is not always obvious why certain actions occur

Justify - Show adequate grounds for decisions and conclusions and answer the main objections likely to be made about them.

Link - This is often a neat way of dealing with some types of data where you think there is a relation but the relation itself is not known with any certainty. One often finds this kind of activity evidence in a matrix formulation or representation.

Outline - Give the main feature or principles of an object, omitting minor details and emphasising structure and arrangement

Portray - This might be a useful verb if you were looking for types in a study. For example, if you were looking for people who get involved in illegal downloads one might want to portray them in some way.

Profile - This is similar to a description but it focuses on just the key points. For example, if we were looking for best practice in a situation then we might start by just profiling a given task – that is we outline the main steps and rationale to start with. The idea is similar to an outline but implies deliberate selection of certain aspects.

Represent - Sometimes you might plan to build a representation of some event as your primary data. For instance, if one was looking for security awareness in employees then of course one cannot "see" it or collect it as such. In these cases we must try to find a way of representing an awareness level or feeling and that representation forms our data.

Summarise - Give a concise and lucid explanation or account of something, presenting the chief factors and omitting minor details and examples

Synthesise - Resolve something into a whole from its component parts.

3.4 Testing Your Research Design	16
3.5 Example Specifications	16
3.5.1 Example Complete Engineering Project Specification	16
3.5.2 Example Complete Study Project Specification	19
4.WORKBOOK 4 – LITERATURE REVIEW & STRATEGIC IT VALUE NOTES/EXAMPLES	23
5.WORKBOOK 5. LITERATURE REVIEW	25
5.1 Plagiarism	25
5.1.1 Identifying Plagiarism	25
5.1.2 Common Critical Devices	26
5.1.3 Common Literature Tools	26
5.1.4 University Review Assessment	26
5.2 Review Content	26
5.3 What goes into a Literature Review	27
5.4 Integrity and Evidence	27
5.5 Literature Sources	28
5.6 Basic Writing Rules	28
5.7 Literature Assessment	28
5.7.1 Literature Review Structure	28
5.7.2 Literature Review Construction	29
5.7.3 Literature Review Traps and Pitfalls	30
5.7.4 Reference and Bibliography	30
5.7.5 Evaluating Internet Resources	31

5.8 Citation Examples	32
5.9 Literature Reviewing Cautions	33
6.WORKBOOK 6 – MAJOR PROJECT ELEMENTS	35
6.1 Scope and Scale	35
6.2 Presenting Problem	35
6.2.1 Defining the Problem	35
6.2.2 Defining the Problem - Example	35
6.2.3 Cautions on Problem Definition	36
6.2.4 Problem Size	36
6.3 Project Target	36
6.4 Project Outcome	36
6.5 Problem, Theory (Speculation) and Form	37
6.6 Primary Data	37
6.6.1 Primary Data Collection Protocol	37
6.6.2 Project Purpose in a Nutshell	38
6.6.3 Pre-processing Primary Raw Data	38
6.7 Writing a Research Question (Study Projects)	39
6.7.1 Questions that are not Questions	39
6.7.2 Basic Research Question forms	39
6.7.3 Research Question – Why are we asking it?	40
6.7.4 Research Question Form of Answer	40
6.7.5 Strategy for formulating a Research Question	40
6.7.6 Function of a Research Question	41
6.7.7 Meaning in a Research Question	41
6.7.8 Common Errors in Research Questions	41
6.8 Primary Data Generation with BAGeD	42
6.9 Getting a BAGeD	42
6.10 Research Question, Form of Answer and BAGeD Examples	43
6.11 Writing an Hypothesis	44
6.11.1 Formal Experiment	44
6.11.2 Informal Idea	45
6.12 Writing an Aim and Objectives	45
6.12.1 Project Aim	45
6.12.2 Project Objectives	46
6.13 Words needing care in Aims, Objectives or Research Questions	47
6.14 Writing a Title	47
7.WORKBOOK 7 – BASIC RESEARCH METHODS CHECKLIST	48
7.1 Research Styles	48
7.2 Research Approaches	48
7.3 Research Outlook	49
7.4 Which Method to Use?	49
7.5 Research Basic Purpose	49
7.6 Rationale: Case Studies	49
7.7 Rationale: Vignettes	50
7.8 Rationale: Action Research	50
7.9 Rationale: Experiments	50
7.10 Rationale: Quasi-Experiments	51
7.11 Rationale: Surveys	51
7.12 Rationale: Biographies/History	51
7.13 Rationale: Grounded Theory	51
7.14 Rationale: Ethnography	52
7.15 Rationale: Requirements Gathering	52
7.15.1 The Requirements Document	52
7.15.2 Stakeholders	53
7.15.3 A Process Model	53
7.15.4 Requirement General Questions	53
7.16 Research Design	53

1. WORKBOOK 1. MASTER'S PROGRAMME OUTLINE

The Master's programme has two units of study: Research Methods and Project and the online programme notes together with this workbook pack cover all the information you need to complete it.

1.1 University Expectation

The University expects that when students submit work it is the very best they can do. In practice this will mean several things and all of them will be examined when work is assessed.

English – written English must be of a Master's standard and that means an IELTS score of at least 6.6 (or equivalent) is needed. If submitted written work is judged to be below this standard, students will NOT be allowed to progress to the project stage no matter what their actual language certification states.

Structure – work must be well structured and coherent. In practice students will most often work with a pre-defined set of headings and they must be used explicitly without deviation in their implied content.

Preparation – good work can only be produced if there has been adequate preparation. This will mean a thorough study of any and all references and exercises. Study does not mean a quick read through the notes or academic arrogance which says "I don't need it" or "I know all this stuff". This preparation also means working through the topic idea itself so that one becomes expert in a particular field.

Instructions and Guidance – all the work you submit will have to meet various standards in terms of layout and format and students are expected to following such guidance diligently.

Using other people work – all work submitted must be the student's own but within that work they may refer to the work of others but all material used must have proper attribution. Thus, if another author's work is copied, paraphrased or summarised it must be properly cited. Students need to understand that paraphrasing (putting things in your own words) and summarisation will amount to plagiarism if not properly attributed. This is a very serious matter and the rule with regard to copying is very simple. If 6 or more words are copied then the sources must be cited and if 10 or more words are copied without attribution then that is regarded as proof of plagiarism

Student's Own Work – the submitted work must be entirely constructed by the student and to do this it is necessary to weave into ones own ideas and thoughts the work of others. One may use the work of others to lend support to a proposition, or to include a definition or an explanation and so on. In other words it is not so much a question of how much of another person publication one uses but what one does with it in constructing ones own research work. In short scholarship is acknowledging and using the work of others whereas plagiarism is using the work of others and in so doing attempting to fool the reader into thinking it is ones own.

Respect – when writing one is doing it for another person to read and it's therefore a grave sin in those circumstances not to offer the very best one can produce.

Need - only quote, paraphrase or summarize when it is clearly adds to what one is saying and it is not just common knowledge or obvious. The key task is to formulate ones own ideas, in your own words by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

1.2 Overview of Unit Assessment

The two units: Research Methods and Project are assessed separately and students must in each one gain at least a pass grade in order to qualify for a Master's award. The assessment artefacts are.

Research Methods Unit (15 Credits)

The Research Methods Unit will be taught over approximately 12 weeks and assessment details will be published to you early in the Unit. The assessments are as follows.

Assessment 1a - development of a project specification plus a short literature review

Assessment 2 - a coursework on statistics.

Project Unit (45 Credits)

The Project is an extended research exercise where students will be guided by a personal supervisor. For students who have passed assessment 1a, approved projects will start a few weeks after the end of the Research Methods Unit and last for at least 18 weeks. There is only one assessment as follows:

Assessment 1b – prepare a full research based project document based on the specification developed in assessment 1a. The details of what is required in the Project itself can be found in Workbook 9.

1.3 Research Methods Unit Assessment Overview

This unit of study requires about 150 hours of effort from each student and will cover research principles, research ideas, research techniques as well as statistics. Assessment details and due dates will be made available early in the study period for the Unit in WebCT.

1.3.1 Assessment 1a – Preparation, Literature Review and Project Specification Development

The first unit event will be related to the development of a project specification and is in two stages.

Part 1 – Project Proposal Approval (up to 10 marks) – when the Research Methods unit begins students need to gain approval for a project title/idea. The university will supply a list of ideas or students may bring one of their own as long as the related project outcome has a strategic business IT dimension, it is new work, it involved learning in IT and it is a Master's level activity. In the approval process students have to write a short submission to a set format and send it in a plain email to the Research Methods tutor whose decision is final. This process must be completed by the due date set in the Assessment 1a papers (normally about week 6)

Students are permitted ONE attempt to gain marks in each cohort at this stage and one of three outcomes is possible:

Approved – the submission, whilst not necessarily being perfect, meets all the above project criteria and the outline is judged good enough for the student to begin work on the specification. About two weeks after approval is granted a supervisor will be allocated who may assist you in finalising the project Specification.

Permitted – the submission has a suitable idea but its construction is judged to be of poor quality but the student is given the benefit of the doubt and is expected to make good in the specification. No supervisor will be allocated and final approval will be depended on the quality of the final specification.

Rejected – the work is received after the due date or submission does not meet the criteria for a project in this degree and a new topic must be chosen and a new application made. Most often this is because there is no Strategic Business IT, the project research is regarded as trivial or plagiarism is detected.

Part 2 - Online Self Tests – these will be available at set times for a set duration every week for the first 5 weeks. Typically 1 mark will be awarded for each test in which you score 65% or better. Students should note that missing any test for whatever reason means the recorded score will be set to zero automatically as there is no provision for taking the test at another time or by another method.

Part 3 – Short Literature Review and Specification Approval – based on an approved or permitted project proposal students prepare a short literature review and full project specification which must be posted into a WebCT drop box on or before the assessment due date. The Research Methods tutor will review the work and write a feedback report for each student. The specification and feedback report will then be placed before a University panel who will decide whether it is appropriate for a Master's level project. At the end of the specification approval process one of four outcomes is possible:

Approved – students with an approved project proposal will have their named supervisor confirmed. Students with a permitted project proposal status will be allocated a supervisor. The supervisor will be automatically sent a copy of the feedback report and specification. Approval will not mean that a specification is perfect and it is expected that students will take note of any feedback given by the Research Methods tutor or the allocated supervisor to further refine it.

Approved Conditionally – students with an approved project proposal will have their named supervisor confirmed. Students with a permitted project proposal status will be allocated a supervisor. The supervisor will be automatically sent a copy of the feedback report. Conditional Approval means that there are some significant concerns that must be addressed before work begins and students are expected to redraft their specification, based on feedback given by the Research Methods and in discussions with the allocated supervisor.

New Topic – this means that a student specification has been rejected in its entirety and another topic must be chosen and work must begin again by seeking approval for the new topic before writing a new specification for submission in the next available cohort. This action is most often used when the University decides that the work is trivial, or the work has no significant IT content, or the student has submitted a specification without gaining approval for the topic, or plagiarism is identified.

Plagiarism is Identified – no approval is given and the relevant student work is subject to review by a disciplinary panel. Plagiarism is a form of deliberate deception in order to gain advantage and will always be treated with the utmost seriousness and may even result in students being dismissed from the course.

1.3.2 Assessment 2 - Statistics Coursework

This is usually a set of questions and mainly deals with quantitative data. The submission date will be published to you.

1.3.3 Calculation of Research Method Unit Mark

The overall mark for the Research Methods unit will be calculated as a weighted average for assessment 1a and 2 with the actual calculation being $0.7 \times \text{Assessment 1a percentage mark} + 0.3 \times \text{Assessment 2 percentage mark}$ in which a pass is indicated by scoring 40% or more overall.

1.4 Assessment 1b - Master's Project

This unit of study requires about 450 hours of effort, guided by a University appointed supervisor and based on the specification developed earlier in the programme. The actual project document must be supplied in the form shown in section 9 of these notes and is expected to be of about 15,000 words maximum (excluding appendices).

Once allocated a supervisor, students will be asked on what date they wish to submit their project. The only rule regarding project activity is that it must last at least 18 weeks and no more than 2 years but it will be a matter for students to negotiate with their supervisor and the University to agree a submission date. Students are allowed to make small changes to the specification during the project process but they must be approved by the supervisor and must not amount to a change of the topic that was approved.

2. WORKBOOK 2. RESEARCH METHODS CHAT AND STUDY PLANS

This is a general plan for study for this course. Chat sessions are important because they are collective and interactive and typically focus on just one important feature of research and to get the best out of the course students need to prepare properly. That means reading the notes, doing the multi-choice tests that go with each chapter, studying the Workbooks and contributing if you can to the discussion boards.

2.1 Contact Mechanism

Contact with students is through email, discussion boards or chat. Email is very important and you should ensure that you use an Internet based service so that you can get mail almost anywhere. It is good practice to create an email account just for the duration of the course and a common choice is GoogleMail because the storage space is, for all practical purposes, unlimited. If you are not able to create a GoogleMail account let me know and I will send an invitation to you. It is important that only ONE email account is used for communication and that address is made know to the Research Methods tutor as follows.

Whatever, mail system you use it is advisable to set mail forwarding from both your WebCt accounts to your personal one to ensure that you get mail as soon as it available. It is also useful if students have a Skype or IM account as many tutors allow direct access if they are online. Skype is preferred since chat, voice and video are all catered for and during contact one does not get bombarded with advertising. Internet email services vary considerable but my recommendation is that you only use a service that:

- Provides a virtually unlimited storage capacity
- Guaranteed to work from almost any location: hotels, Airport, etc
- Allows you to set a mail forwarding address (most services do not so check this with care)
- Provide quality SPAM filtering, virus checking and is not on the SPEWS blacklist
- Allows POP redirection (so you can use Outlook and send from databases etc)

2.2 List of Workbooks Sections Available

Here is a list of all the workbooks in this pack. Students must read them as the course progresses and tutors will expect a committed familiarity with what they say.

No	Workbook Name	Comments
01	Master's Course Outline	General overview of course and assessment structure
02	Research Methods Chat and Study Plans	Lesson plans for the chat sessions and student study plan
03	Project Specification Notes and Examples	Shows what a submission should look like with some helpful hints
04	Sample Literature Review and comments	Shows what a submission should look like with some helpful hints
05	Literature Reviewing	Guidance on constructing a review
06	Major Project Elements	Notes on writing a clear aim and a set of corresponding objectives
07	Basic Research Methods Checklist	A list of several possible research methods for quick reference
08	Bibliographic Referencing Harvard APA	Notes on how to use and cite source literature
09	Writing Up a Research Project	Sample content outlines on how to write your project document
10	Project Submission Form	A checklist to use before project submission
11	Marking Form Study Format	A copy of the form use to grade your project submission for reference
12	Marking Form Engineering Format	A copy of the form use to grade your project submission for reference
13	Project Mark Reconciliation Form	A copy of the form to reconcile marks when markers cannot agree
14	Supervisor/marker notes and grade criteria	Use by supervisors and markers to assess project work
15	Unit Level Feedback	Form that allows you to give feedback on each unit you study
16	Research Methods Master Notes	Complete course notes as a pdf file (not in this pack)
Table 1. List of Workbooks		

2.3 Complete Study Plan

Students must work in a committed way for the 12 weeks during the Research Methods unit and submit the work required on the set dates – there will be no extensions given other than for sickness or other indisposition (in which case students need to complete an ECF and provide documentary evidence of incapacity). Failure to deliver on time without permission will mean that the student unit result will be recorded as a fail. For the whole course the timings in hours are approximately as follows:

Course Element	Time	Comments
Chat Sessions	25	Including preparation and summarizing the chat log
Regular Visit to Site	25	For email and discussion board
Study Notes/Text Book	35	Including making notes and doing the tests
Preparing Submissions	65	Including reading the relevant workbooks and topic details
Table 2. Overall Research Methods Unit Study Plan		

2.4 Recommended Timings for Completing the Research Methods Work

Please look at the following list of times for preparation and carefully plan a way through this unit using these estimates.

Course Element	Time	Comments
Statistics Questions	20	There will usually be 4 questions for you to work through.
Literature Searching	10	The key to a successful submission of the assessments is that ones mind is fully prepared with all the knowledge needed.
Task Description	5	Here students prepare a project proposal: the research question, the form of answer expected, the Basic Activity for Generating Data, data specification and decision on a research method.
Project Idea Approval	5	The format used for this can be found in the Assessment 1a description
Research Plan	5	Here students prepare a plan for collecting primary data. This is not literature searching, it is new and original research
Short Literature Review and Project Specification	20	A partial short literature review and comment is provided in Workbook 4. The Project Specification format is presented in Workbook 3.
Table 3. Coursework Submission Plan		

2.5 Recommended Five Week Development Plan

In this course students must write a project proposal as soon as possible using the format set out in Assessment 1a. However, the basic project idea must be developed and refined carefully and typically it will be done in the sequence shown in table 4 where items in blue are specific to Engineering and items in red specific to study projects. Typically this refining process start is week 3 of the course

There is NO short cut in this work and the standards are very high. The expectation is that you will read and study the notes, examples and exercises with dedication and care. Failure to study with care is usually obvious in the quality of the work prepared, so work hard and think through carefully all the steps below – there is NO substitute for thinking your own idea through. There are plenty of examples to guide you but these examples are not templates they are there to help you gain understanding and not as some sort of quick fix to the work.

If the University sees in your work that all you have done is copy the example substituting a few words here and there then it is very likely your submission will be rejected. The University is looking for students who are thoughtful and careful in their work and through a process of hard work each student must demonstrate commitment high standards – nothing else is acceptable.

Week	Work Recommended
2	<p>Topic Area Research – this is about thoroughly understanding the topic area in which your problem is set. For example, if one was looking on Inventory Management using IT in a fast moving retail environment. that is where your literature research efforts are to be directed. So one would look at inventory management itself, warehouse based systems, shop shelf systems, POS systems, tracking fast moving but small value items, restocking, forecasting, re-ordering and so on. The idea is that you take time to think of all the aspects of the topic and then you try to become knowledgeable in them. There is no short cut here and the work must be done thoroughly and with commitment.</p>
3	<p>Presenting Problem Definition – every project will be based on a real-world problem of some kind. Student must define the problem as accurately as possible and that will be the theme of this first work element. Notice the intention is to have just ONE problem definition. (See Workbook 6 section 6.2 and 6.5)</p> <p>Target – this is the intention of solving the problem itself – that is what real-world benefits will result. For example, the problem might be about accuracy in inventory records and that would imply that if we can find a suitable project outcome that can be used to alleviate that situation then it will results in the target of for example reduced inventory costs. Problem and target are two side of the same idea. (See Workbook 6 sections 6.3)</p> <p>Research Question – here one tries to encapsulate the problem definition and ones theorising into a concise and lucid question that will form the focus of the research effort. (See Workbook 6 section 6.7 and 6.9).</p> <p>Theorizing based on the problem Theme – here one theorises about possible causes of the problem and corresponding solutions. In the case of inaccurate inventory records we might theorize solutions as being based on: production of a training plan for staff, feasibility report on possible use of technology, development of a sales policy and so on.</p> <p>Project Outcome Form – during theorization choose what might be regarded as a best solution and this becomes the single outcome intended for a project. For example, if we take the problem mentioned above of inaccurate inventory records then a project outcome could be a feasibility report on the use of RFID as this might be seen as a way of solving/partially solving the stated problem. (See Workbook 6 section 6.4 and 6.7)</p>
4	<p>Primary Data Definition Outline – the primary data definition is affected by means of the BAGD and it needs to be focused on the problem definition and the expected form of answer. (See Workbook 6 section 6.6, 6.8 and 6.9) In Engineering projects the outcome will be an application of some kind and that needs to be described.</p>
5	<p>Aim and Objectives – in the aim and objectives you sharply focus ones project by stating the means whereby one gets the major project outcome by a series of minor ones in order to achieve the project real world target. Of particular significance here is that the distinction between a project outcome and a project target is thoroughly understood. (See Workbook 6 section 6.11)</p>
6	<p>Research Design – this is the core of any project and it is the place where one expects to see serious and consistent thinking about how the presenting problem is to be resolved by collecting and processing primary data in order to generate the expected project outcome that will eventually lead to a real-world benefit called the project target. There are three elements as follows. (See Workbook 3 section 3.2, 3.3, 3.4 and either 3.5.1 or 3.5.2 as appropriate)</p> <p>1. Research Method Selection – this is an overarching framework used to guide and control the research effort. There are many Research Methods and it is necessary by a process of logic based on ones Research Question and it primary data needs to select and justify a suitable method. For Engineering projects the research method is focused on collecting application requirements. (See workbook 7)</p> <p>2. Design of Primary Data Collection Plan – based on the Basic Activity for Generating Data which focuses on the core data needed and then that basic activity surrounded by a process that allow reliable collection of the primary data. (See Workbook 3 section 3.5.2). For Engineering projects the plan is based on the outline application proposal which focuses on the core requirements and outlines a process or processes that allow reliable collection of the requirements. (See Workbook 3 section 3.5.1)</p> <p>3. Design Primary Data Processing Plan – with a collection of primary data in some suitable form one can apply some processing to it in order to arrive at the expected project outcome. Typically this might be statistics if the data is quantitative, various forms of text analysis or diagramming if it is qualitative. (See Workbook 3 section 3.5.1 or 3.5.2)</p> <p>For example, if one conducted a survey on the effects of SPAM on personal productivity then this might have been done with a questionnaire with say 20 questions. Now processing each question and drawing charts and graphs is NOT the same as explaining the effects of SPAM on productivity – to do that one must consider the whole survey where each question would be a dimension of the problem space. It follows that typically one pre-processes the data collection in some way and later using the results of that pre-processing we further process the data to get the intended outcome</p>
Table 4. Specification Elements Work Plan	

2.6 Critical Reflection

Students must expect to go back and forth over their work because as knowledge and understanding grows one will inevitably see that some of one's earlier work was incorrect or not as clear as it could be or maybe it can be improved in some way. This revision strategy is very important as a common fault with research work is that it often lacks consistency because there was no serious reflection on earlier work.

2.7 Chat Session Profiles

The following is a simple guide as to what students will be covering in the online chat sessions. These sessions are extremely important as they are usually interactive and are based on using examples. The research Methods Unit will involve a chat session roughly once every week – half these sessions will be based around the notion of research methods and half based on statistical processes.

2.7.1 Chat Session 1 – Setting up a Project?

This chat session will be a discussion of what is meant by research. The chat will focus on the idea of a presenting problem, target and outcome as the basic project building blocks. From this the chat will move to discuss a framework to surround a research project and a look at some of the core techniques that must be mastered. To prepare for this chat read Workbook 1 and 2 and Workbook 6 section 6.2 to 6.6.

2.7.2 Chat Session 2 – Refining a project Idea?

This chat will take the form of a discussion on how a project idea is explored and focused and a full example will be used followed by an open discussion and questions from students.

To prepare for this chat, students should be familiar with the title approval format shown in Assessment 1a and the specification examples and notes shown in Workbook 3 sections 3.5.1 and 3.5.2. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea. Of particular concern in this chat is the notion of presenting problem Workbook 6 section 6.2 and form of answer (project outcome) in Workbook 6 section 6.3 and 6.7, Basic Activity for Generating Data Workbook 6 sections 6.8 and 6.9. Students must work hard on these three ideas if they are to form an acceptable project specification.

2.7.3 Chat Session 3 – Research Method and Research Designs

In this session a research design will be developed based on a personally developed problem definition, research question, form of answer and Basic Activity for Generating Data. To prepare for this chat students should be familiar with the title approval format shown in assessment 1a and have studied the specification examples shown in Workbook 3 sections 3.5.1 and 3.5.2 as well as the associated notes in section 3.1. It would also be useful if students had some idea of the area in which they want to work so that they can map the various exploratory elements on to their own idea.

2.7.4 Chat Session 4 – Literature Reviewing and Working in a Scholarly Manner

In this session some examples of student work and how they write down their ideas will be examined based on scholarly principles. This will be followed by looking at a process that applies equally to what one writes and what one reads. The remainder of the chat will examine several excerpts from student work that exhibit common faults. To prepare for this chat read workbook 8 on citation styles and bibliography, chapter 4 of the notes and Workbook 5 and it might be useful to read through the sample short Literature Review in Workbook 4. In addition, it will be useful if one look at one's own way of using primary source materials and find some examples that are good and bad.

2.7.5 Chat Session 5 – Aim and Objectives

This chat will focus on how to write an aim and a set of objectives based around a problem definition and a Research Question. To prepare for this session read Workbook 6 sections 6.11 and Workbook 9 section 9.6.3 but also consider one's own project idea and what might be suitable in that case.

2.7.6 Chat Session 6 - Open

This chat will look back over the course and typically review faults that arose out of the assessment of the project specification. This will be supplemented by a discussion as to how various project elements: title, research question and Basic Activity for Generating Data, aim (not aims) and objectives are constructed but focused on the basic Activity for Generating Data.

2.7.7 Extra Chats - Open

Normally, each week there will be an open chat on Sunday at 1400-1500 where students may bring their questions, comments, concerns or grumbles. These are useful sessions but only when students come prepared with items that they need to discuss. These are not teaching sessions so the tutor will have nothing to say unless students come prepared with questions and are willing to participate.

3. WORKBOOK 3. PROJECT SPECIFICATION NOTES AND EXAMPLE

This section contains some guidance notes and sample completed project specifications - please consider them carefully. Do NOT copy them blindly – they are just for guidance and students must write their own in a way that matches what they want to do. The aim of the specification is to state a project plan as clearly as possible so one needs to be concise and precise.

3.1 Project Styles

In projects two styles are commonly found. There are some restrictions on these two forms depending on what programme you are on but the Tutor will advise on that issue. Briefly the two styles are as follows:

Engineering – here you design and build a software application, create a system design etc.

Study – here you design a research program to collect primary data in an attempt to find an answer to an interesting question. For example, one might investigate whether cascading styles sheets lead to simpler accessibility or you might evaluate the role of email management in business success.

3.2 Specification and Design

The following notes and samples for project specifications may help you prepare your own. However, it is important to think of it as being primarily a design for your project. The specification is essentially in three parts although it is not presented in exactly this sequence:

Preparation – this is not explicit in the specification but implies that you have thoroughly reviewed the literature at least to the depth of feeling confident that you know enough about the project topic to define and gather data. Implicitly, the University will look at your use of the literature and reference list to assesses how prepared you are for this work at this level and on this topic.

Background – this is about you setting the scene and defining a problem and then focusing on that problem with a Research Question, aim and a set of objectives.

Research Design – this is the culmination of the specification where you set down your detailed design for defining, collecting and processing primary data to get your stated form of outcome. It is very important to realise that this is a design and without a sound design things are likely to go very wrong.

In summary, one needs to think of the whole processes as starting with a problem definition and ending with a solution (your project outcome) and the element that connects these two things is your research design. It follows that unless you have a good design you will not be able to get from your problem to your outcome and that will mean your project fails.

3.3 Project Specification Headings and Formatting

All the following main headings and subheading must be used and students must not introduce others. As these guidance notes are read it is advisable to also look at the relevant examples in section 3.5 so that one can clearly understand what is being said.

3.3.1 Specification Header

Make sure all your details are entered correctly otherwise work may be misfiled or rejected because we cannot ascertain whose work it is.

3.3.2 Project Title Construction

Project titles must make clear sense in English and not be overlong. See Workbook 6 section 6.13.

3.3.3 Specification Intention

This element is to be a simple statement regarding whether there is an actual real world client for the outcome of this project or if it has some other purpose.

3.3.4 Project Task Description

The main function of this section is to explain what is going to be done using the suggested headings below and as shown in the sample. The headings are intended to be precise and if students ignore or change them or use them for any other purpose the work will be rejected. The actual selection of headings will depend on the type of project: Study or Engineering.

Engineering Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct an Engineering project task description and must expect to go over them many times before a concise and useful description is formulated. For Engineering projects please note that a functional description means that one says what the application will do for the users and not how it might be built or what architecture is involved.

Situation Overview – express here a concise and high level description of the existing or proposed application area.

Presenting Problem Definition – a concise definition of some real world problem related to data processing of some kind. This is an important step since unless one can clearly see what the problem is then any solution suggested may be deficient in some way. In most cases the problem definition in engineering projects is related to elements such as data availability, searching, access speed, storage, processing, accuracy, sharing, reporting, entry, updating, deletion, control, security, volumes, segregation, consistency, worker efficiency, process systematization, communication and so on. For the purposes of writing a specification the expectation is that students will focus their problem definition on one major aspect of the application scenario. See Workbook 6 section 6.2 and 6.6.

Real-World Target – a summary of the real world effects that are expected if this problem can be solved or partly solved.

Application Proposal – expressed as a concise description of the main system functionalities. When describing the main functionalities it should be done at a high level and it is recommended that they are all coherent and there should be no more than 10.

Ethical Overview – express here a concise review of any ethical impacts of gathering the primary data, processing it or system usage.

System Architecture – a concise description of the major or main architectural elements of the proposed application

Strategic Value – expressed as a concise argument that the application is able to deliver to the stated problem definition.

Study Projects Headings

Students are recommended to use these headings carefully in a step by step manner to construct a study project task description and must expect to go over them many times before a concise and useful description is formulated.

Project Topic Area Overview – a concise description of the topic area aspect being covered.

Situation Overview – a concise, high level description of the context in which the research is set.

Presenting Problem Definition – expressed as a concise statement of the single underlying problem leading to this study. This is an important step since unless one can clearly see and define what the problem is then any solution suggested may be deficient in some way. Study projects look at an aspect of strategic business IT and that might cover technology effectiveness, IT investment, user acceptability, development or improvement plans, feasibility studies, legacy systems and so on. See Workbook 6 section 6.2 and 6.6.

Real-World Target – what desirable real-world benefit is likely if the stated problem can be resolved or partially resolved. (See Workbook 6 section 6.3)

Research Question – expressed as a concise question that captures the problem definition and the real-world target. See Workbook 6 section 6.7 and 6.9.

Personal Theory – expressed as a concise and focused rationale regarding what an answer might be to the Research Question. See Workbook 6 section 6.5.

Intended Project Outcome – write a concise statement that expresses the expected major project outcome as it arises out of the stated problem definition and your personal theory and would be an answer to the Research Question. See Workbook 6 section 6.4, 6.7.4 and 6.9.

Strategic IT Value – here it is necessary to discuss ones intended project outcome and show that it is or leads to a Strategic Business IT impact that could eventually resolve the stated problem definition and hence generate a Strategic Business IT value. See example in Workbook 4.

Ethical Overview – a concise review of any ethical impacts of gathering the primary data, processing it, presentation or usage of results in the form stated

3.3.5 Overall Project Aim

This is a vital point in the specification because in a very concise manner a researcher brings together in one aim: the main project **activity** to get a stated project **outcome** as well as telling us what **data** is the focus of the activity and finally what the purpose or **target** for the project outcome is in relation to real-world problem resolution. It is essential that you fully understand these four elements as described in Workbook 6 section 6.11, 6.11.1 and Workbook 9 section 9.6.3.

3.3.6 Set of Project Objectives

To meet an overall aim it is necessary to achieve a number of milestones indicated by a set of objectives generating minor outcomes. Objectives can be hard to write and it is expected that there would be between 3 and 6 of them. See Workbook 6 section 6.11 and 6.10.2, Workbook 9 section 9.6.3.

3.3.7 Research Design

The Research Design is about the core elements that generates primary data and processes it into the form of answer expected (your project outcome). The Research Design is divided into two phases.

Design for Collecting Primary Data – a process or processes used to define and create a primary data collection. It has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the actual data and present that data.

Design for Processing Primary Data – a process or processes used to manipulate the collection of primary data to get the form of answer expected.

A useful analogy for a Research Design is that it is like deciding that you want a sponge cake and then working with a shopping list (a list of primary data that you want) to collect a bag of ingredients (collection of the listed primary data). Once we have our ingredients (primary data) we use a recipe to prepare and mix them (pre-processing the primary data) ready for the final processing step to bake the cake (like generating your form of answer). To reverse the analogy, if you were going to make a cake you would not walk into a shop and just pick up a random set of ingredients and then mix them all together into some muddle, bake it and expect a cake to emerge - no one but an idiot would do that would they?

The suggested headings to use are as follows and you are recommended to use them carefully in a step by step manner to construct a research design. You must expect to go over them many times before a concise and useful design is formulated. In the examples I have added the step numbers for clarity but you do not have to do that in your own work as long as all the elements are present.

Engineering Projects Research Design Format

Research Design Phase 1 – Requirements Collection Process

This phase is concerned with a process that generates a reliable collection of primary data which in an engineering project will be a set of requirements. See Workbook 7 section 7.10.

Define – here one bases the definition of requirements on the outline proposal document.

Location – state where or from whom the requirements can be found.

Collection Protocols – here it is necessary to select appropriate collection protocols such as: interview, observation, records searching and so on needed to collect the requirements under the standard four headings: Functional, Non-Functional/Performance, Technical and Usability. See Workbook 6 section 6.6.1.

Requirements Presentation – the requirements data once collected will typically be presented as interview transcripts, notes and copies of documents and lodged in the project document appendix as a kind of requirements catalogue.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulate it to get a design for the application. This is in two sections.

Overview – show how the various requirements are expressed in a design.

Specific – in any design there will be aspects that have no obvious means of expression and such aspects are typically written as a list.

Study Projects Research Design Format

Research Method – make a selection and write concise rationale for its use. See Workbook 7.

Research Design Phase 1 – Primary Data Collection process

This phase is only concerned with generating a reliable collection of primary data and is based on the Basic Activity for Generating Data but to be it has to be surrounded by a complete process.

Basic Activity for Generating Data – a concise description of the activity that forms the core of the primary data collection process. See Workbook 6 section 6.8 and 6.9

Primary Data – outline primary data items to be collected. See Workbook 6 section 6.6.

Location – a concise description of where the primary data may be found. In practice it may come from almost anywhere including extraction from existing secondary sources.

Collection Protocol – a concise description of the actual collection procedure which may be based on one or more of the following: interviews, questionnaires, observation, roles playing, document analysis and so on. See Workbook 6 section 6.6.1

Primary Data Presentation – expressed as a concise description of the way in which the primary data will be presented.

Research Design Phase 2 – Processing and Presentation

This phase is only concerned with a processing the collection of primary data in order to get the expected project outcome.

Design of Pre-Processing for Primary Data Collection – concise description of the processes applied to the raw primary data collection to generate a refined collection of primary data structured in a fashion that makes it suitable for generating the intended project outcome. (Workbook 6 section 6.6.3) (Please note that this step will not always be needed)

Design for Primary Data Presentation – presentation of data collection generated from the pre-process step - if that step is not needed just a presentation of the primary data.

Design for Generating the Intended project outcome – here the primary data collection (pre-processed if necessary) is used in some algorithmic or heuristic fashion to generate the intended project outcome.

3.3.8 Logistics and Tools

In this section the practicalities in terms of tools and time need to be considered. It is only necessary here to state things that are specific to this project, so it is not required to say things like: the library, Word, Excel, paper, pen, SPSS and so on as these are common and almost always available everywhere.

3.3.9 Outline Content List for your Project

This should be detailed enough to ensure that there is a clear idea of the final structure of the project document. Please be careful with the essential elements as indicated on the marking forms since if they are omitted a significant number of marks may be lost in the final project. See Workbook 9 table 6 and section 9.3.5 where typical chapter and section headings can be found. Workbook 11 or 12 (marking forms) need to be consulted so that no essential elements are omitted

3.3.10 References

This section is used to assess how well a student has prepared for the project activity. The University will want to see that the reading is current, comprehensive and focused on the topic area. It is expected that work in the specification will be supported from the literature particularly in the outline description and research method sections. Unless the literature is seen to be used in the various sections of a project specification it may not be approved although it is not expected that one cites from every book in a reference list. See Workbook 5 and Workbook 8 and make sure citations are in the Harvard APA style.

3.3.11 Project Plan

The plan must be developed by looking at ones contents list and considering what activities are necessary to generate the various project objects. Aim for around 12 to 20 activities lasting at least 18 weeks with any suitable start date. A project activity is something that is significant and requires planning and monitoring. So for example:

Prepare Metric Program – this is clearly a significant activity that has to be planned and monitored and so properly part of the plan

Select an Organization – this is an activity and might be important but it is doubtful if there really is a significant process involved here that has to be planned and monitored.

Outline Implementation Plan – this is not an activity so should not be in the plan.

The University will examine each plan and will want to see that it is focused on the project – the implication here is that it should be possible to see that a given plan supports a particular project idea not juts a copy of one of the samples or is so generic it might apply to any project.

3.4 Testing Your Research Design

A design must amount to a logical plan that takes a problem definition to a description to the expected outcome that will resolve the stated problem. The following are a useful check that a plan is sound.

Practicality – consider whether one has the resources to be able to carryout a plan. This is a very serious step and must not be taken lightly. It is all very well to have an elaborate plan on paper and to think because it all sounds logical that it can actually be done. In many cases a crucial test of practicality is to be sure that one can get the data from the locations specified.

Credibility – here one is expected to be honest and decide whether the plan will result in useful data and outcome. It is unfortunately true that many research projects end up being trivial because of poor identification of data and more importantly the choice of appropriate collection protocols. It is also worth considering the data processing functions as they must also be credible.

Confirmability – this test is about what would happened if the same research was done a second time with the same data – would the researcher end up with the same answer. To put it another way, is the processing method too dependant on an individual and that dependence may lead to bias.

Trustworthiness – here we are concerned that the conduct at all stages is such that one could have confidence that the results are genuine and not manufactured.

3.5 Example Specifications

Here are some sample specifications, they are complete except for the contents list and project plans but they are not meant to be copied without any conscious thought and any obvious attempt to do so will result in specification rejection.

3.5.1 Example Complete Engineering Project Specification

Here is an example engineering specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Literature Review & Project Specification (Engineering) – Jan Smith 341387 MSc Computing

Detail - jan.smith@port.com for Cohort Started March 2006 (Word Count = 2,414)

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Intention – the customer is SIS and the application is expected to go live by June 12, 2006.

Project Title - An Assessment Marks Processing Application. (See Workbook 6 section 6.13).

Situation Overview

Currently, the core processing is done by staff members dealing with their own assessment marks, typically using Excel. The staff member then forwards his marks sheets, usually in paper form, to the administration office where the marks are collated using Excel to give an overall score for each student. These two marks sheets: individual unit marks and overall student marks are then presented to the Board of Examiners for scrutiny and acceptance. The process ends when a transcript is sent to each student detailing their results for that semester.

Presenting Problem Definition

The actors feel that the root problem is about consistency and accuracy given the sensitivity of the data but coupled with difficulties with storage, retrieval and reporting. (See Workbook 6 section 6.2 and 6.5)

Real-World Target – the desired effects here are that consistency and accuracy are both improved but at a reduced workload. (See Workbook 6 section 6.3)

Application Proposal

Based on the presenting problem there an application is needed that can offer us consistency and accuracy in the processing of assessment marks, both by unit and by overall student performance. The system to be called a mark processing system and it will have the following main functionalities.

Functional Requirements

1. Store name, address, year of study, name of course and unit details of all registered students.
2. Store the assessment patterns for each unit including weights and pass mark.
3. Allow for the entry, updating and deletion of any or all records.
4. Allow for the entry of assessment marks for individual entry or by batch updating via CSV
5. Report on marks for each unit including basic statistics.
6. Report of overall student performance, including basic statistics.
7. Produce student transcripts.
8. Provision for other ad hoc reports at a later date.
9. Secure access to individual results to be available to students through a portal.

Non-Functional and Performance Requirements

1. Store records for at least 6 years.
2. Allow for at least 6 simultaneous users
3. System must be capable of processing all the data and providing the reports within 10 working days. The estimated current volume is 145,000 data entries and 139 reports but this is expected to grow by about 7% per academic session.

Technical Requirements

1. Be developed in MS Access 2003.
2. For use under Windows XP.
3. All processing activities, including reporting, to be carried out using native Access facilities.
4. All processing is to be done using Access VB and no macros are to be used.

Usability

1. Be developed using normal windows formats and standard colours.
2. Fonts use in screen to be no smaller than 9 point and standardised at Ariel Narrow.
3. Assumed screen size to be 19".
4. Report to be printed as appropriate but with fonts never less than 10 point.
5. Data entry load per screen to be as recommended in DEF 981.90.
6. There should be some consideration of access via the portal for the visually impaired.

Ethical Overview

The collection of requirement here does not present any ethical problems. However, when in use the system contains personal and sensitive data and this aspect must be considered in the design

System Architecture

The intended application is essentially a database system with a web link. It will therefore have two interfaces: one a direct link to the database through the Access application and the other through a secure web interface routed through a portal but with only read access.

Strategic IT Value

The proposed application and its functionalities should address the presenting problem very well. In particular controlled data entry, data storage and reporting. This should reduce administration overheads and costs in a cost-effective manner.

Aim

To build an assessment marks processing system using standard MS products in order to ensure consistency and accuracy in the processing of student results. (See Workbook 6 section 6.11 and 6.11.1, Workbook 9 section 9.6.3)

Objectives (See Workbook 6 section 6.10 and 6.10.2 and Workbook 9 section 9.6.3)

1. To produce a detailed, departmentally based, marks processing requirements document.
2. To produce a detailed marks database design using standard documentation protocols.
3. To produce a detailed assessment functional design to include data entry, updating, deletion for marks processing and reporting.
4. To design the secure portal for student use.
5. To produce and evaluation report of the marks application.

Research Design Phase 1 – Requirements Collection Process

This part of the research design is concerned with constructing a reliable primary data collection for later processing into the form of answer expected. In this case the primary data collection is a set of detailed requirements for the marks processing application. The primary data that we need is related to the proposed major functionalities stated earlier and given to us in the form of a proposal. For each of the functionalities it is now necessary to decide. (See Workbook 7 section 7.10)

Location – The requirements can be found at various locations in Portsmouth. In particular

Detailed Functional Requirements: the appropriate targets for this exercise are: SIS office administrators, departmental course leaders, individual academic staff, Heads of Department and the University registry (for regulatory aspects). It may also be useful to make contact with a number of external examiners to ensure that the reporting arrangements are acceptable. In addition there will be various documents such as regulations and marks sheets

Non-Functional and Performance Requirements: the appropriate targets here are the Registry since they set examination and graduation dates as well as define the necessary reports. The office senior administrator also needs to be consulted for staffing and usage issue. During this process there must be detailed discussion with the department and the Registry over security issues as this is a major ethical issue. In addition there will be various documents such as regulations, external examiner reports.

Technical Requirements: the appropriate target here is the departmental technical to establish hardware and software profiles. It may also be necessary to discuss network and security issues with the University central computing department. It may be necessary to see network and PC specifications and various security profiles.

Usability Requirements: the basic design is based in Windows protocols so there are no particular requirements to be gathered. However, because it is possible to implement interfaces in a few ways particular usability requirements will be ascertained by use of a mock-up used with the administration staff. With regard to the Portal there will need to be discussion with the University webmaster over formats and protocols to be used. In addition there will be various documents defining standards and formats.

Collection Protocols – The collection is essential a survey format where each requirement aspect will be discovered by just three formats: (See Workbook 6 section 6.6.1)

Detailed Functional Requirements: expressed as interviews, document analysis (marks sheets and regulations) and some observations. It may also be necessary to use observation to examine any existing Portals.

Non-Functional and Performance Requirements: interviews, document analysis (marks sheets and regulations) and observations.

Technical Requirements: interviews and document analysis (system specifications and profiles)

Usability Requirements: interviews and document analysis (system specifications and profiles). In addition it will be necessary to run some focus groups to look at various interface design option by means of mock-ups.

Requirements Presentation – the requirements data once collected will be presented as interview transcripts, notes and copies of documents. These artefacts will be reviewed and a tabular format used to present the requirements and lodged in the project document appendix.

Research Design Phase 2 - Design Presentation

This part of the research design will take the whole collection of requirements and manipulates it to get a design for the application. This is in two sections.

Overview – here the vehicle used to present the various requirements in a design format will be UML. The mechanism will be to take the written requirements documents and map them to a suitable diagrams in the form of use cases, class diagrams and where appropriate collaboration or sequence diagrams.

Specific - where necessary a written list will be provided. These will mainly be used to state unambiguously the various non function, technical and usability details.

Logistics and Tools – Required Resources

All the hardware and software are available at the Client's premises and all work including requirement gathering will take place there. The major products needed are: Dream weaver and MS Access and scripting will be done using ASP.

Outline Content List for your Project

See project guidance notes for samples and they can be found in Workbook 9 section 9.3.5 and table 6 but you must also be aware of the marking forms that can be found as Workbooks 11 or 12.

Project Plan

Any clear format may be use but a typical format (but not events) can be found at the end of the Study Project sample specification.

3.5.2 Example Complete Study Project Specification

Here is an example study specification. It is for guidance only and students must not try to copy it since it is unlikely to match their own project idea. However, the headings and sub-headings must be used in any submitted work.

If it is obvious that a student has just copied part or all of this specification the work will be rejected. Students MUST think through their own idea step by step and the University will be looking for evidence of serious thought and commitment.

Literature Review - Include your short Literature Review here. (See sample in Workbook 4)

Project Specification (please start on a new page)

Intention – no customer involved and project results will be used to produce a research paper.

Project Title - Quality Control in Program Development - A Possible Strategy (Workbook 6 section 6.13).

Project Topic Area Overview

There is much interest in Software Quality assurance at present and this is for obvious reasons. Software applications are unlike normal products which wear out and can be tested over time to see where most wear takes place and hence calculate a mean time between failures. By this means failure can be effectively prevented by maintenance. However, in software such wear does not occur although an analogue of this is when other hardware and software components around the software, or the application itself changes and hence problems arise. Typically, we test program code and the more we test the code the more certain we become that it is robust.

Situation Overview

The research is set in The University of Portsmouth with the School of Information Systems. In that context it will focus on the programs produced by first year computing undergraduate students.

Presenting Problem Definition

The problem for developers is focused on knowing when code is robust and ready for release. (See Workbook 6 section 6.2 and 6.5).

Real-World Target

The benefit that would accrue in the real-world if this problem can be resolved or partially resolved is that developers can feel more confident about their product and therefore not risk costly development overruns and compensation claims from clients. (See Workbook 6 section 6.3)

Research Question

How can developers feel sure that software applications are ready for release in order to prevent costly overruns and client disappointment? (See Workbook 6 section 6.7 and 6.9)

Personal Theory

The topic is fraught with difficulty because there is no accepted way to measure program code to see how good it is or even to see if it is correct. Blithe (2002) explains that it is well understood that it is not normally possible to measure, using an interval and ratio scale, in any meaningful way the quality of program code. However, it might be possible to find some means of 'indicating' the quality of the code in the sense that one might be able to pick outliers by taking certain kinds of measurement. It is therefore suggested, that simple measurements of various code properties might be used to pinpoint outliers and hence shorten the testing cycle by transforming the measurement statistically into a pseudo Interval and Ratio scale form which is called Planar Similarity. (See Workbook 6 section 6.5).

Intended Project Outcome

It is expected that the form of the answer arising out of this theory will be a demonstration in the form of a report with graphical evidence that endorses the proposition that Planar Similarity is an appropriate software quality indicator in that outliers can be detected hence assuring the measurement process. (See Workbook 6 section 6.4 and 6.9)

Strategic IT Value

If Planar Similarity is indeed a useful measure of software quality it can be used routinely to examine software in production and give an early indication of quality and that will lead to shorter test cycles and hopefully more reliable software installations and a consequent reduction in cost. In fact Clitheroe (2003,p6) has suggested that detecting all code faults at the initial coding stage might save as much as 23% of development costs. (See example in Workbook 4)

Ethical Overview

There are no current users of the process being developed there would not seem to be any ethical consideration of importance. However, it is necessary to explain to the students supplying the sample programs the purpose of this study and assure them that none of this information will be used for assessment and allow them access to the results if they so wish.

Aim

To report on the efficacy of the Planar Similarity measure using simple metrics as a means of finding outliers in program code and hence reduce coding errors leading to development cost reduction and client approval. (See Workbook 6 section 6.11, 6.11.1 and Workbook 9 section 9.6.3)

Objectives (see Workbook 6 section 6.11 and 6.11.2)

1. To model the software construction process.
2. To report on appropriate simple and synthetic metrics that might be used as indicators of quality in application programming code.
3. To define a process that will extract the defined metrics for any piece of code.
4. To document a suitable statistical process for reducing the metric value set to just two dimensions.
5. To analyse and report on the data, including outliers, and hence derive some general conclusions regarding the utility of the Planar Similarity metric.

Research Design - Research Method

The chosen method will be case studies since I want to see the impact of the measurement process within a defined context and of particular interest in that context is student programmers with differing abilities in writing business application style programs. The case criteria are simple and amount to selecting a sample of students at a set point in their first year of study and a set of matched programming tasks. (See Workbook 7)

Research Design - Phase 1: Primary Data Collection Process

This part of the research design is solely concerned with constructing a reliable primary data collection for later processing into the form of answer expected.

Basic Activity for Generating Data

The basic idea is to compare a new piece of code with an existing piece that is known to be sound and take a series of measurement on each one that might highlight any differences and so indicate an outlier. The idea has some support based on early studies carried out by Sheene (1999) who noted that a reasonable means of indicating quality in program code is to compare similar pieces of code by calculating several metrics for each piece although he did not define how this might be done practically. (See Workbook 6 section 6.8, and 6.9)

Primary Data

This study will define 20 software metrics which will be calculated automatically and for each sample programme. The metrics that form the primary data collection for this research will be such things as: function density, function count, cyclomatic complexity, data associations, decision count, decision density, number of variables, number of function calls, etc. (see Workbook 6 section 6.6)

To set up the case studies three computer program specifications will be drafted with the students working in 'C++'. The specifications will be written so that the defined software application is, in each case, of a different style and progressively more difficult. An expert in 'C++' will produce a set of generics to match the requested programmes – it should be noted that a generic is an outline or skeleton of certain kinds or classes of program.

Location – The sample frame is all first year students on computing courses at Portsmouth University. This is around 350 students and my calculated sample size is 200 students, however, since the data collection process is automatic all 350 students will be used in this study.

Collection Protocols – The collection is essentially a survey format where the students will be given the relevant generics and the specifications and asked to write three computer programs of increasing complexity, one in each of three semesters. In this case there is a large data set to be collected and it is not practical to do the collection by hand. In view of this an application will be written that will process each student program so that metrics may be calculated automatically and stored in a suitable electronic file. Students will be requested to deposit their programs on set dates into an online drop box for both marking (not part of this study) and metric calculation. (See Workbook 6 section 6.6.1)

Primary Data Collection Presentation

The sets of primary data will be available in the project document appendix and will be presented in tables where the rows represent the sample programs (one row for each sample) and the 20 columns the metric values.

Research Design - Phase 2: Processing and Presentation

This part of the research plan will take the whole collection of primary data and manipulates it to get the expected outcome form, which was a demonstration that outliers can be detected hence assuring the measurement process. The processing is in three steps: manipulate the raw primary data, presented the processed data in graphical form and extract from the graphs features by manual inspection.

Design of Pre-Processing for Primary Data Collection (Workbook 6 section 6.6.3)

The metric data sets will be read directly from the files produced in phase 1 and then statistically processed to define a similarity measure for each program using principal component analysis and multidimensional scaling. The outcome of this processing will be pairs of values, one pair for each sample program, suitable for plotting in two dimensions.

Design for Results Presentation

The pair of values from the first processing round will be plotted in two dimensions, together with the results for the generics producing three graphs one for each program specification.

Design for Generating the Intended Project Outcome

Once the graphs are available it is then a simple matter to look for outliers in particular and attempt to explain their distance and orientation from the generic and other programs in the class. The contention is that similar programs will cluster together and ones that are different (even though the specification was the same) will show up as outliers and can be identified and examined to see why that difference occurred. It is hoped that the results will be similar for all three program in that data set and hence demonstrate that complexity is independent from planar similarity.

The final step is to use the identified outliers to go back to the actual program code to explain why the code produced the outlier. In this way it will be possible to get an indication of why a given program is deficient. This final processing step allows me to generate my report on Planar Similarity that contains my overall findings and evidence on its utility.

Logistics and Tools – Resources Required

All the hardware and software are available at the University. Since the data collection process is automatic the use of staff resources is minimal.

Outline Content List for your Project

See project guidance notes in Workbook 9 section 9.3.5 table 6 but you must also be aware of the marking forms that can be found as Workbooks 11 or 12.

4. WORKBOOK 4 – LITERATURE REVIEW & STRATEGIC IT VALUE NOTES/EXAMPLES

This is a sample of what is expected in assessment 1a, however, it only shows two elements: the strategic business IT statement and the short Literature Review. Try to keep in mind that this is just ONE example and do not try to copy it blindly or try to fit it into what you want to do.

Strategic IT Value

This work was based on trying to resolve or partly resolve the problem of low quality code leading to the need for costly re-work at later stages in the development cycle. The importance strategically of this work is that the outcome: a definition of new software metric will imply that it is possible to identify poor application code and this can be done at an early stage in the software development life cycle. The importance of this is that corrective action can be taken early in the development cycle and as a consequence costly re-work late in the cycle can be avoided or reduced. A secondary or added value element is that the results will allow the identification of good programming standards and this in itself will also lead to improvement and strategic advantage on all products delivered.

Tutor Comment

The key element here is that one relates the expected outcome or form of answer to its use in resolving the problem theme that was the basis of the project, and hence demonstrate a strategic business IT value. Failure to create a clear argument based on the problem theme and outcome leading to a strategic business IT value will mean loss of marks.

Literature Review (See Workbook 5 but note section 5.6 in particular)

Hiskett in his 1987 seminal paper on metrics defined several apparently useful metrics, the best known of which are 'program vocabulary' and 'program length' which are essentially metrics that count operators and operands and their usage in a given piece of code. Hiskett's metrics are easy to calculate but he was unable to show any strong correlation between his measures and program quality as defined by experts in the field. Similarly, Rogers and Hamerstein tried to use Hiskett's metrics as predictors of MTBF in accounting software but the results were inconclusive and no link could be found between the metrics and the type of software (functionality), accounting in this case, and the metric used.

Garlick, Sheene and Southwood (1999, p450) attempted a new approach that involved the notion of similarity, which they called planar similarity – that is two programs could be defined as similar because: they are written in the same language or they perform similar functions or they were written to the same standards or they are written to the same specification or they were written by the same team or finally they perform the same function. Their work is aptly summed up in the opening paragraph of their paper:

"The nature of any true measurement is easy repeatability and this implies that the style of measurements form a suitable metric space. This means that we need to define the nature of the similarity before we define a measure. In principle this is simple since it is easy to name the similarities but in practice it has been difficult to articulate a precise definition."

The similarities described above deserve further explanation but here only two of them in combination are used: similar language and similar or same specification. Similar language is easy to understand but at first glance it would seem that if two different programs are written to the same specification they are bound to be the same. However, after a little thought, it is obvious that if two different people write two different programs to the same specification the programs are certain to be different in many respects. It follows that the basic, though loose, hypothesis is that if planar similarity can detect a similarity (alternatively difference) in these programs - written to the same specification but by different people - it might be possible to use planar similarity to detect differences between two or more programs against any defined mode of similarity. Conversely, if it cannot be shown that a similarity exists between two or more programs written to the same specification then there is no hope whatever of showing any other kind of similarity with this metric.

Two final points need to be considered: what exactly is meant by software quality and why would a similarity measure be a good indicator of quality? To answer the first question we have only to refer to Kitchenham's 1998 paper where she defined five kinds of quality, briefly:

Transcendent View – quality is a kind of innate excellence, something felt rather than seen.

Product Based View - quality is related to the content/attributes of the product.

User View – quality is seen as equivalent to fitness for purpose.

Manufacturing Based View - quality is equated with conformance to specifications.

Value Based View - provide product at an acceptable price and conformance to a specification.

In this study the transcendent view was the one chosen as the basis of the definition of quality. The meaning of this view is defined by experts in the field – that is, can an expert in, say, Java programming make a judgement as to whether a given piece of code is good or bad – well, here it is argued that such an expert can and does such tasks routinely. Curiously there is very little literature on this idea of expert opinion within the software community but Gavin as early as 1978 touched on the subject. However, it is a reasonable conjecture and it will be used in this study – interestingly, if it can be shown that planar similarity can detect similarity (or equivalently differences) then it would also support the conjecture that experts can judge software quality.

Finally, the study will rely on the ability of experts to judge quality in software. This judgement is exemplified in the production of exemplar or generic programs. Garlick (2003, p98) has written extensively on this subject and the work is well known and will not be fully reviewed here. However, it is possible to define classes of program modules - validation, input, calculation, reporting and so on – it follows, that using the idea of similarity it is useful to create a standard or *generic* program or module for each class. Such a program can then act as a base line for all planar distances related to its application class and hence be a measure of similarity (or difference).

Using Garlick's idea we can let experts define our generic and then use that to compare with other programs – if we declare a difference then in simple terms we need to look at that program because it might be of poor quality and conversely if we declare no difference then we can fairly conclude that the program is sound.

Tutor Comment

The literature review is supposed to be a student's own work. As such it is a discourse that outlines the major areas of a topic area but amounts to an essay which is the student's alone. In practice this means that students must read deeply into the subject and then weave what is read into what the student already knows or believes in order to create a useful summary of the topic that will form a strong base for carrying out the actual primary data research - this implies that you 'master' the subject area and become expert in it.

It follows from the above that if all you do is copy or paraphrase from various sources without any significant comment or analysis on your part then it amounts to plagiarism and is worthless.

One final point is that when you write up your review in your final project document you should use various sub-headings and other formatting elements to structure the section to make it readable and meaningful.

5. WORKBOOK 5. LITERATURE REVIEW

The main function of this review is to ensure that one's mind is prepared with all the specific problem area knowledge that it needs to carry out the project and its primary research. In practice this implies the rather difficult task of integrating different ideas, theories and experiences into a thematic, informative, complete and clear discourse on your chosen subject area.

Preparation of the mind is done through adding your critical evaluative comment on what you find in the available literature and such critical reviews are typically hard work and not about downloading a few articles from the internet. The key characteristic of the greatest thinkers in history was absolute and unswerving honesty in all their thinking and that principle has never changed. They used their intellect and reasoning abilities to the full. They were honest no matter what the subject be it religious, political, business or academic. These men would not accept dogma from religion, politics or academic sources without subjecting it to serious critical questioning and of course this often meant great suffering for them.

5.1 Plagiarism

The KEY is honesty – without that your work is worthless – you may be able to fool some people but as Shakespeare said “This above all: to thine own self be true, and it must follow, as the night the day, Thou canst not then be false to any man. So when you plagiarize I may not know, the University may not know but YOU will always know that you obtained something falsely.

Plagiarism means passing off other people's ideas as your own. In academic life, it is one of the worst things that anyone can be accused of, as it is a form of stealing or cheating. It is fully expected that students will carry out research prior to completing a piece of work. This may include the use of books, journal articles, reports, manuals, notes and so on as source material. The material may be public, restricted to a closed set of people or with a security classification), or privately communicated. The principles are the same whether the material is on paper or in an electronic format. When you refer to an idea in a piece of your own work, it falls into one of several categories:

Common knowledge - many people know it and the information does not belong to anyone person but it cannot normally be deduced by you it has to be learned. It is probably talked about in several sources: the world is round, computers contain both processors and memory, OO is routinely used in software construction and so on. If you are sure that it is common knowledge, you do not need to cite a source. Be careful, authors will often write down in their own work things that are common knowledge so quoting them in that instance amounts to saying that a bit of what is common knowledge actually belongs to that author and that of course is an absurdity.

Obvious – many people know it and the information does not belong to anyone person but it can be deduced. It is probably talked about in several sources: companies tend to grow as time goes on, when the sun goes down it gets dark and so on. If you are sure that it is obvious you do not need to cite a source. Be careful, authors will often write down the obvious in their own work so quoting them in that instance amounts to saying that what is obvious to every one actually belongs to that author and that of course is an absurdity.

Published – this refers to an idea that found in a specific source or sources which is not common knowledge nor obvious but is nevertheless useful – in these cases you must always cite the source or sources of such an idea.

Original – you may include freely original ideas of your own. However, be aware that if the reader sees an idea that is not cited and is not common knowledge nor obvious, then they are entitled to believe that either it is a new idea published by you or you have plagiarised it.

5.1.1 Identifying Plagiarism

Plagiarism does not occur only when you copy words verbatim. Plagiarism is about ideas, and even if you express the idea in your own words, you may still be guilty of it if you do not credit the source. However, expressing an idea in your own words might often be good scholarship. The difficulty is that anyone can copy and paste a phrase, sentence or paragraph and cite its source. This is technically not plagiarism, but it's often very poor scholarship since it is obvious that such an activity tells us nothing about the learning, if any that has occurred

Scholarship is about showing your understanding and criticism of ideas. Simply copying, paraphrasing or summarising can only show understanding only to a limited extent. You need to "add value", that is make your own contribution to knowledge, to what you've read and you can usually only do this by expressing an published ideas in your own words and mingling them with your own thoughts and ideas.

5.1.2 Common Critical Devices

The essence then is to infuse your work with your own thoughts and ideas and let these mingle with what it is you have found in the literature. The most common forms of this are:

Interpretation - explaining and expanding on what you have found.

Criticism – discussing in order to judge whether the ideas are good or bad.

Decomposition or Analysis – to tease out the constituent parts of an idea.

Synthesis – by means of discussion and explanation link separate ideas together.

Selectivity - showing which ideas to include and which to discard.

Abstraction - taking an overview or defining a model or framework, usually by looking at examples.

5.1.3 Common Literature Tools

The following are the most common means of incorporating, in a scholarly fashion, the work of others into your own written work (a fuller discussion of these tools may be found in the notes).

Copy – use the exact words using quotation marks. A good rule is that each quote holds a single main idea, which you want to use and then you must introduce it and then follow it up with discussion.

Paraphrase – expressing something that you have found in the literature in your own words - the intention being to simplify, explain, or interpret a complicated idea. But take care there is a very fine line between simplifying, explaining and translating something and just being lazy.

Summarise – producing a précis or abridgment of a part of the source we have found. Essentially one is trying to capture the main points in an argument.

Analyse – the purpose here is to offer a detailed examination of some whole by scrutiny of its parts.

Synthesise – here the idea is to take parts and put them together into a new whole for some purpose.

You might find it useful to remember: copy in order to discuss, paraphrase to simplify, explain or interpret, summarise to capture the main points, analyse to understand and synthesise to build something new.

5.1.4 University Review Assessment

When the University looks at your Literature Review it will be trying to decide if you are committed and prepared for the topic and working at Master's level. If your work is poor in terms of structure, content and form you will find yourself failing. This is NOT necessary so long as you put in the work and ensure you understand how to use citations and the literature. I want to encourage you to do good work - it will ensure that you pass well and it makes your work a pleasure for the Examiners to read.

5.2 Review Content

The review is about your topic area and about you becoming sufficiently expert in it to deal with the problem that you will have uncovered. The intention is for you to offer a discourse that is focused, relevant, authored, measured, evaluative and expressed as a dialogue. (Notice the acronym FRAMED)

Focused – this means that your whole effort is focused on the topic area and the particular aspect of it that you are pursuing. So do not be tempted to add in other things just because they might be useful, interesting, and novel or you just have nothing else to say.

Relevant – any topic area aspect will itself normally represent a large body of knowledge and so one needs to continually ask if a particular element in the knowledge domain is relevant to your particular study.

Authored - any literature review is to be written by its author. This sounds obvious but it is all too easy to fill up a review with cited quotations, paraphrases, summaries and so on so that the 'hand' of the review author is not evident anywhere in the work. When this happens it is not an evaluative review at all but simple plagiarism. The author's 'hand' must guide and direct the review in an evaluative fashion so that the review is a message from the review author and not a recitation of what has been found elsewhere.

Typically this is done by using ones own skills and knowledge to introduce, comment, add to, modify and extrapolate from various primary sources available.

Measured – this is a matter of selecting and using the focused and relevant materials that you have found. Unfortunately, It is all too easy to pack in information in excruciatingly precise detail and so end up with a laboured entry that treats your readers as if they where completely ignorant of the subject area. So here one needs to just say honestly “is the entry a measured response to my and my readers, information needs”.

Evaluatory – authors sifts through the primary sources looking for materials to use. The essence of this sifting is an evaluatory outlook based on an awareness of your problem theme and your topic area. Care is needed because this process is not about searching for materials that you agree with or like in some way. Instead it is a contextualised response (what do you already know) and that may mean you find materials that are new to you, materials that make you change your own knowledge base and often materials that completely replaces what you thought was solid.

Dialogue – a review is a form of argument because good ones are based on a strong theme and in them one is trying to explain to, and convince your readers about something and so it is best if you think of it as a kind of dialogue in which you vicariously challenge them about your review theme and content.

5.3 What goes into a Literature Review

It will depend to a large extent what it is you are working on and what you want to say but the following list give some common ideas of content.

Challenge – this is two way: what you read challenges you and you challenge what you read for validity and applicability and so one might find new ideas or change our perspective.

Consolidation – reading widely consolidates your own knowledge base in that it can confirm or show any gaps in your knowledge.

Exploration - implies searching for new ideas, theories, concepts, rules and so on.

Self Check - affirm what we know for currency and accuracy

Support - the reading might support or be in opposition of ones views

5.4 Integrity and Evidence

This heading sums up research - integrity because it must be your own work and evidence because you MUST be able to show that your results have value. There are basically 4 strands to good work as follows

Dogma – this simply means things you have to take at face value. Most often they are things that are not open to reason in the sense that one is not allowed to question them and in some countries you can find yourself in serious trouble if you do. The problem with dogma is that by definition there is no logical support for it. Just to use a simple example, some faiths require you to have a beard or not eat pork as a matter of dogma – in such cases we usually cannot logically deduce that this is a right or wrong thing. It may of course be simpler than that since we all invent our own dogmas from time to time – for example it may be very simple such as ‘I will never buy a Ford car’.

We all accept dogma but that really is not the issue – the issue is that we should not accept it without some critical thought. There is at least one rational way of exercising critical thought on dogmatic issues and that is asking is the outcome of actions based on it good, bad, neutral or at least does not harm anyone. The trouble however, is that dogma sticks to us like super-glue and we will often go to great lengths to defend it and almost always this is done by sophistry (worthless arguments) and of course the notion of what is good or bad is not easy to define.

Reason – this is the ability to be logical and reason about what it is you are reading or writing. That is you are encouraged to ask questions and seek for a deeper understanding. This may imply that you accept new information, modify what you already know or reject something as no longer valuable.

Honesty – here we are talking about not taking things at face value and being honest with yourself about what you are reading or writing and asking does it all make sense and is it coherent with what I already know.

Motive – this aspect is about your reasons for wanting to read or write something. Now such motives can be high minded or they may be base. One must therefore always guard against tendentiousness (the author simply wants to convince a reader of something and may use any means to do it) in ones own writing and be watchful for it in the writing of other.

5.5 Literature Sources

The available literature is classified broadly speaking into the two kinds described below and ideally we only want to use primary sources.

Primary Sources – that is the first published documents. One can be really pedantic and say the real primary sources are the author's manuscript or autograph but these days we are satisfied with published sources. It will however, often be difficult to establish that something is indeed a primary source.

Secondary Sources – in almost every document you see, there will be elements attributed to other authors – these are then secondary sources.

Be careful not to confuse the above definition with those for primary and secondary data. When we talk of primary sources we are obviously referring to something that is published and exists whereas with primary data it will not exist until a researchers defined, locates and collects it.

5.6 Basic Writing Rules

For Study projects a full literature review will be needed but for Engineering projects the requirements document forms part of the Literature Review. However, even in Engineering it is necessary to write a short review just to form a technical backdrop to your project. It may help you to remember there are two cardinal rules when writing – they are simple:

Respect – always have a deep respect for ones readers and make it easy for them to understand what you are saying.

Need - only quote, paraphrase or summarize when it is clearly adds to what one is saying. The key task is to formulate ones own ideas, in your own words but one does this by building on knowledge of, and an evaluation of other people's ideas, not just repeating them.

5.7 Literature Assessment

When assessing this element the University will look at how YOU use the sources in what you write and at the range of sources that you used. If either is judged deficient your work may not be accepted as the view taken will be that you are not prepared for work at this level and on this topic. It is expected that all your sources will be mostly primary ones. If there is some reason why this is not possible it must be discussed with the Research Methods tutor or your project supervisor.

5.7.1 Literature Review Structure

All the following steps are iterative and you must expect to go backwards and forwards many times before you get a review with which you are happy.

List – Make a list of all the various topic strands that you need to know about. It may help you to think about strands such as: organisational, administrative, functional, social, technological, cultural, ethical and so on or some other structure best suited to you topic. Remember, this is not about writing down everything you know it's about giving your readers a focused discourse on your chosen topic area

Arrange – Use your prepared list above and put the topics into a logical and progressive order.

Theme – Decide on a theme that will link all the various topic strands together.

Structure and Content – Now use your themed list of topics and structure what you write using headings, subheading, paragraphs, bullets, tables, diagrams and so on.

Reading/Writing with the Intellect - This is normally thought of as a four stage process that applies equally to what is written (because it is going to be read by someone).

Understanding – this is simply taken to mean that we understand the words used.

Interpretation – are able to find meaning in the words used.

Evaluation – we ask does the meaning have any value – in essence we ask is it true or false.

Contextualization – this implies that everything we read is coloured by what we already know. This idea is taken much further in the idea of hermeneutics (see the notes).

Usage – the literature that you find and evaluate can be used to supplement your own work and demonstrate your mastery of the topic area. This does not mean that you quote, paraphrase or summarise everything you see. As a rule of thumb: only quote, paraphrase or summarise when it is necessary and it is not common knowledge and it is not an obvious observation.

Argument - Finally, keep in mind that when writing you are dealing with a form or argument where you are trying to persuade your reader about some point or other and that should only be attempted when you are knowledgeable, the argument is essential and you have a deep respect for your readers.

5.7.2 Literature Review Construction

Here is a plan that you can use to construct your own review. It is not infallible and will require conscious effort from you and it must be based on a thorough evaluation of the literature.

Step 1. Purpose - the purpose is to fully prepare your mind with all that you need to know about the topic area and the particular element of it that you are focusing on. The idea is that what you write shows your mastery of the topic and in fact you have become an authority on the topic area. So a review is not a long list of quotes, paraphrases and summaries, it is an evaluatory discourse. That is, readers will want to know what YOU have to say based around what you have uncovered in the literature - so readers must see what you have found and see what you have to say about it.

Step 2. Topic and Aspect - Make sure you are clear about your topic area and which particular aspect of it you need to explore and understand in order to be able to effectively carry out your planned research.

Step 3. Select a Theme - Use your project problem definition, target and outcome to guide you in selecting a theme that will connect all the various elements of your review together making it a lucid and progressive discourse. (Don't be afraid to alter the theme as you go along if that becomes necessary)

Step 4. Your own Views - Try to make a list of your own views, ideas and knowledge. Remember, the review is an evaluation of what you find not a recitation of it. If all you do is tell us what you have found you may not even pass because almost anyone can write a review on any subject if all that is required is to more or less recite what has been found. So you must structure the review around your theme and your own ideas and thoughts.

Step 5. Make a Review Content list - Based around your theme make an outline list of things to include and then arrange the list into an order that will take you progressively through the topic area aspects. Commonly it is found that it is useful to start as follows.

5a. Basic definitions and terms that need to be clear for the core topic area. (Be careful to note any abbreviations)

5b. Map out several important areas or problem space dimensions. Now it is impossible to be general here so for example if I were looking at mobile devices and their use in business I might map out the following elements: value, attitude, use, limitations, practice cost, ease of use, learning curve, effectiveness and so on. Please be careful here to look for significant things not just drag in anything and everything. Once you have made this list you may add to it, modify it or discard from it as you go along.

5c. Work out how you want to end the review - often this just sums up your point of view but you may have other ideas

5d. You may like to include some statistics if that is relevant. But don't let this run away with you and so the review just becomes some sort of justification based on statistics. Remember, statistics almost never tell us anything about the topic itself and only tell us things related to the relative importance of certain things we have identified.

Step 6. Literature Searching - Armed with your theme and list of elements now start your search for suitable material but be very careful to record the exact details of where everything may be found and checked. The search may start with the Internet or a special tool like Google Scholar but must move on to respected publications.

Step 7. Structure - The step is to structure what you have found and what you want to say about it so we get a coherent and lucid discourse on your chosen subject area. This is not a trivial matter and you must expect to go over it many, many times before it is really an example of your very best work.

5.7.3 Literature Review Traps and Pitfalls

Most of the things listed below are regarded as due to simple laziness and so are unforgivable in a Master's student or indeed any research student and if you are guilty of them then expect severe punishment in terms of loss of marks or failure overall.

Not a justification - A literature review is NOT a justification for your research idea or problem definition. So filling the review up with various statistics will never be regarded as explaining to the reader the topic area and your evaluation of it.

Statistics - Filing up the review with statistics carries no real value in convincing the markers that you are master of that topic area.

Poor Structure - where the review is little more than a few drafts notes obviously written without much thought. To communicate you must impose some structure on what you write else the readers will not be able to see any progression in your thought or in the topic.

Filling up the review with citations - one after the other with no student input. It is correct and desirable to tell your readers what you have uncovered but unless you make comments and add your own views on what is found the work will be regarded as worthless.

Common knowledge and Obvious - Quoting or paraphrasing material that is either obvious or common knowledge implies that you have not looked at the sources beyond the first page or forward. Here is an example from a project document. "Poston (2000) stated that organisation expected ERP systems to deliver improved performance". This is worthless as it is obvious that they would want this and to say it makes no valuable point at all - its no good trying to say things like this as if Poston was enunciating some law of the Universe or a point of huge importance on some new and valuable angle related to ERP - no he is just stating the obvious.

Bad citations style - It is very common unfortunately to see the citation form (Briggs, 2000) placed at the end of a sentence or paragraph. When we see this it can ONLY mean that all you have done is paraphrased, summarised or copied that section. This practice is more or less plagiarism and is representative of a very lazy attitude that assumes that just expressing something in your own words is a valuable contribution - its is not because YOU are saying nothing and what you are supplying is not really your own work at all.

Activity Definition - Some students use the Literature Review to tell us what they are going to do in the research. This will result in a zero mark as what is to be done is covered in the Research Design so repeating it here is valueless. This practice is a certain sign of laziness.

5.7.4 Reference and Bibliography

References are to primary sources that you use in the text of your written work. A bibliography is a list of sources you have identified as useful, including references, but not necessarily used. The University will look very carefully at any references to see if you are prepared for study at Master's level in your chosen topic area. Overall, the expectation is that you will list at least 10 sources. For each source you must consider its:

Currency – looks at publication date and be aware of changes in technology.

Completeness – Make sure you are looking at the final version not some draft or abstract.

Uniqueness – is the source a primary one

Coverage – Use your list of sub-topics to ensure that you cover all the areas required so that you are fully prepared. But make sure that you are not including multiple texts with essentially the same content.

Range – Make sure you have a good range of authors.

Authority – ask is the text authoritative. This can be done by considering the author, publisher, writing style and currency. It is also possible to use citation indexes to see how often the source has been used.

Accuracy – Is the information correct? If you cannot be sure then you must not use it.

Relevance – Make sure that your sources are relevant to your project topic.

Usage - The basic usage strategy is:

Find – Relevant texts using a library index, the internet, online book stores and so on.

Evaluate – Once you find a possible source you must evaluate it for content and relevance.

Contextualise – that is fit this new source into your personal knowledge base.

Cite – If you use a source it must be listed in your reference section and cited in the text correctly.

Discuss – You may include something from a source in your work as a copy (quote), paraphrase or summary but in all cases you must introduce it, comment on it at cite its source.

5.7.5 Evaluating Internet Resources

When using internet resources it pays to be careful and always sceptical because of the following factors:

Anarchy - anyone can publish just about anything on the Internet

Validation - authors do not always have their materials checked by an authoritative third party

Tendentious – when the author wants to convince you of something and will use any means to do it.

Honesty - authors may not always be what they seem and may assume personas, lie or make false claims

Consider – the motives of those who publishing on the Internet

Trust - in research trust nothing until you have good cause to do so. This is the opposite of what we do in our daily lives in that we tend to trust until we have reason not to

Context – be aware of the context of what you find. For example is it a University site, is it a manufacturer and so on.

Accuracy – this simply mean is the information correct. You need to be aware that information might be validly collected but still be quite inaccurate.

Validity – this simply means that we ask is this a valid source in the sense that it was constructed in a reliable manner. Any lack of information on proof readers, editors and publishers means that mistakes are more prevalent than in print and therefore increased scope for innocent error and for outright deception.

Authority – this means was the author competent to create this material. For example any one could have an interest in say Emotional Intelligence and quite easily create an internet article on that subject but it would not have the same authority as that of a University professor who has spent years researching the topic.

Uniqueness – here we are asking is this an original work (a primary source)

Completeness – this may simply be described as asking if the work is the final and finished version. You need to be very careful here else you might find your self using the material from the earlier part of the work which in fact is augmented later in the work.

Coverage – this means what is the scope and scale of the source. Now this does not mean that a source will cover everything on a given topic but it should be clear as to what it is covering.

5.8 Citation Examples

The following set of examples is intended to show some poor use of citations and also some sound ones. These examples should be studied with care by students so that they may avoid inadvertently fall into the trap of using poor scholarly practices. The quotes are from a range of sources and topics and in your study of them you need to concentrate on the form. Now assume all the following were all written by the Research Methods tutor so the comments will be offered in the first person and he is talking to you

These are just simple examples and they do not imply you must use italic or indenting as that is only used here to show clearly the pieces of work being looked at.

Example 1.

Lyau & Pucel (1995) found a link between training and productivity for their sample of Taiwanese car part manufacturers. Bartel (1994) found that training is a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors. Bishop (1994) and Barron, Black & Lowenstein (1989) both found that training increases management estimates of productivity.

This is poor because I only told you what the cited authors said. I did not introduce the author's words, nor discuss them and it's almost impossible for you to see what point I am making other than the obvious one that productivity and training may be linked – in effect it is not my work at all and there certainly is no sense of evaluation here. We might have written

Many authors (Lyau & Pucel 1995, Bartel, 1994, Barron, Black and Lowenstein 1989) found a link between training and productivity and that training is often a preferred and effective strategy for firms to address differences in productivity between themselves and their competitors ... followed by your comments/discussion/analysis etc

Example 2

It has been found that because Arabic words were written by copyists who did not use vowels that over time the meaning of some words has been lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. One way to deal with this is to use assonance and in this paper that approach will be taken (Noldeke 2003, p45).

The problem is that it looks as if I attributed the entire paragraph to Noldeke. So you can have no idea which part of the paragraph was my own thought or maybe none of it was. This is bad practice and some tutors even regard it as blatant plagiarism. The fact is that tutors when they see this form in will automatically assume that all the student has done is paraphrase what he has found and none of it in effect is representative of any student thought and will mark the work down because of it. It could have been written as follows:

There has been a long standing problems with some early Arabic manuscripts in that many words have become obscure and even in context they are still unclear. Bigly and Ahmed (1978, p340) and others have shown conclusively that because Arabic words were often written by copyists who did not use vowel, over time the meaning of some words became lost. Occasionally we also find that diacritical marks varied between different manuscripts and this compounded the problem of understanding some words. It has been usefully suggested by Noldeke (2003,p87) that one way to deal with this is to use "assonance analysis" to study word endings and in this paper that approach will be taken and in particular we will look at some early Arabic poems by Averroes.

You can use the bracketed form if you just want what amounts to passing reference to a source as in the following example.

In two recent works (Harding 1986a, p.80; 1986b, p.138) it has been suggested that ...

Example 3

St. Clair-Tisdall (1994, p45) said in his seminal paper on Organisation Synergy that "change in organisations is an inevitable consequence of growth" – this is an interesting observation and implies continuous IT progression and updating. Knowing this we can support Briggs (1999, p23) who said that OO is now routinely used in the computing industry.

This is poor because the first statement by St. Clair-Tisdal is clearly obvious and that by Briggs is common knowledge. Also it is not entirely clear that the second sentence leads logically from the first one. The point is that using citations here was unnecessary and therefore worthless. *We might have written.*

It is obvious change in organisations is an inevitable consequence of growth and in the modern world that must imply continuous IT progression and updating. Many authors, notably St Clair-Tisdall and Briggs have commented on how these naturally progressive elements may be factored usefully into a company overseas sales policy and....followed by your comments/discussion/analysis etc

Example 4 - Suppose you come across the following in a book by Noldeke. But the bit that interests you is by Frederickson – how will you set about properly using and referencing the Fredricksons quote?

Tools are needed if we are to measure software quality in a meaningful way. The idea of quality, as we know, is intangible since many views are possible. It follows that we must define some terms in order to measure quality. It is useful to note what Fredrickson said: "Definitions of what quantities we need to measure in order to assess software quality are at present arbitrary since as far as we know they have no connection with functionality".

This does not mean that they lack a rationale, but simply that professionals disagree on the definitions themselves and so it follows that

In this case the correct way is to find the Frederickson book and use that because it is the primary source. Quoting from secondary sources will only be tolerated in proven cases where the primary source cannot be found or for other reasons is inaccessible and it must be done in the correct manner as shown in Workbook 8 for secondary sources.

Example 5 – Can you work out what the following extract from a piece of student work is saying?

It is argued that tacitness, complexity, and specificity in a company's skills and resources can generate causal ambiguity in competency-based advantage, and thus raise barriers to imitation (Fahey, 1989). This is to rise a company's distinctive strategic positioning so as to possess some form of sustainable competitive advantage.

The sentences is obviously copied as it is very, very unlikely that any student would write with such academic complexity and obscurity – lines like this are not designed to communicate they are designed to impress the reader not further his understanding. What it in fact it is saying is that some skills are very difficult to duplicate and this may mean that growth may be restricted. We might have written.

Fahey in his 1989 monograph has stated what should be obvious but he nevertheless less shows conclusively that companies often do not realize that some skills are very difficult to duplicate and this may mean that growth may be restricted or if you like it's not all that easy to copy a skill. ... followed by your comments/discussion/analysis etc

5.9 Literature Reviewing Cautions

Writing a literature review is a difficult and time consuming task if it is to be done well and there are no short cuts to sound scholarly work so here are some final pointers.

Laziness - It is very common to see students write down things in a literature review as they occur to them. This practice might be fine for notes but it is obvious that the way thoughts pop into ones mind or information is discovered is most often anything but logical or structured.

Structure – to communicate in writing the work must have an effective structure that is well planned and allows the theme to develop to it natural conclusion.

Pretence - some students try to be scholarly and pack their work with quotations and paraphrases – this then become not an evaluative review of what was found but a recitation of it instead.

Non Review - some students just write down what they know without any references to the literature – this will always lose you marks as no one will believe that you obtained that information by your own brainpower without any outside assistance.

Experience – students often claim that what they write is all down to experiences but again no one will accept that. The way you use experience is in your evaluation of the sources, comments on them and building up your own arguments.

Inclusion – Preparation of the mind for your topic area does not mean you write down everything you know that might be relevant. What it does mean is being focused on your topic area and becoming expert in that. For example, an Engineering project where the literature review contains page after page devoted to telling the reader about every conceivable life cycle is hopeless and in such cases there is almost no thought over what is written and so it is worthless. Similarly, if a study project was looking at eCommerce as a way of selling drugs then page after page telling us about various drugs, treatments and prescribing practices is worthless in the context of just selling drugs. It's not volume is wanted but considered content.

6. WORKBOOK 6 – MAJOR PROJECT ELEMENTS

This workbook is intended to help students formulate clear project elements but here that what is said here is a mechanical process and it is your responsibility to make sure that what is written down makes sense.

6.1 Scope and Scale

Scope and scale are meant to be considered carefully otherwise a project which is out of control and way beyond your capabilities in the time available may occur. Alternatively, the scope and scale may be set so that the problem becomes trivial and the idea is rejected. So please take note of what these terms mean as far as this course is concerned.

Scope – this means something like selection or choice. So for example, if I were looking at training in desk-top packages I might select just Excel or I might select Excel and Access and so on to focus on. The point is I set my scope by being selective.

Scale – the means something like number or extent. So for example if I set my scope as looking at Excel I now need to set the number of users I will include in my study.

Scope and scale are two dimensions that set a frame around your work to bring it into sharp focus and exclude everything else. You need to put limits on both these dimensions but it is most important is to be clear about scope – that is, what exactly to include in your study, normally, just include ONE significant thing.

6.2 Presenting Problem

In any project it is usual to choose an area of knowledge and practice to be its topical focus. For example, one might choose modern usability issues, automated network management, digital paper and so on. Once one has a topic area like this it is necessary to choose a problem theme within it to be a sharp focus for a primary data research effort. It is best if one problem theme is chosen and its resolution or partial resolution would be of strategic business IT significance. In general, it is not all that easy to give a simple and all embracing definition of the notion of problem but the following has proved to be useful.

A problem or issue is something that is a matter of concern or debate within the topic area and whose resolution might bring benefits. (Checkland 2003)

In practice this means a problem is an object not an activity. For example, stating the problem as “how to ride a bicycle” is incorrect since this is not the problem it’s a question about the problem - the problem is “riding a bicycle”.

Another difficulty is that students often write down the problem in such a way that it is an answer or solution to the problem. So for example, if one writes a problem statement as “lack of training” then implicitly that is a solution as well. When this happens it is almost certain that the writer is not thinking about the problem at all but is obsessed with a particular solution. In this particular case the real problem might have been “errors in data entry” and one of many possible solutions is training.

6.2.1 Defining the Problem

It is always quite a good idea to construct one's own definition of the problem and to do it in as few words as possible. Notice, that it is your own definition not one you might look up in a book or on the internet (though you might start with that) because there is often little learning value in just copying a definition as far as deepening your own understanding is concerned.

Remember, that any definition one constructs will not be absolute and universally accepted by everyone - but in research this is not a problem as long as the researcher makes it clear what particular definition is being taken. Do not take this process too far and end up with either over-complicated or trivial definitions - they must be thoughtful and comprehensive. So it is recommended you start by thinking about four things where the acronym CAPE is used:

Characteristics – observable features or facets of the problem idea,

Associations – every problem will have links to other situation elements,

Perspective – when a problem is encountered it will always be from a certain perspective

Effects – say what effects ensue in the real world if the problem is not resolved.

6.2.2 Defining the Problem - Example

Let us suppose that a student has identified the problem theme as Phishing. Naturally, the student will be concerned that this is a good idea and would like confirmation of that before expending time on it. One can

ask the course tutor, but he/she is not expert in everything so at best one would only get an opinion as a response so how should a researcher proceed. So for Phishing a researcher might note the following:

Characteristics: illegal, intrusive, upsetting, preys on those who trust their fellow man, etc

Associations: email, chat, file sharing, etc.

Perspective: management (but try to look at it from several perspectives as well)

Effects: destroys confidences in the system, may lead to personal or company losses etc

Normally, it takes quite a few attempts before a definition that is lucid and comprehensive is obtained. Remember, the definition must also be useful within your research study – that is, it's no good having a well formed definition that does not offer a sound basis for a research effort.

Now here is a first attempt

In the modern world email is a technology that almost everyone uses whether in the home, at work, on the move and indeed it seems to follow one around. Typically, email is a simple one-to-one message passing technology but it is now offered with enhancements that include voice, video, chat, file passing, file sharing where suppliers are attempting to present a complete communication environments. With such a technology come problems and one such problem is identity theft and one way of getting this is known as Phishing. In its simple form an unknown, but apparently authentic, source asks for personal details and then uses them for fraudulent purposes. The problem is identity theft using email systems where a message poses as a legitimate requestor in order to fool the recipient into thinking it is legitimate request. The problem in computer system is known as Phishing.

Here is a final attempt (but most often there are several intermediate attempts)

Phishing is identity theft using email where a personal message seeks confidential or private information from its recipient whilst posing as legitimate request. The intention therefore is to fool the recipient of the message into releasing information which can subsequently be used for fraudulent purposes.

6.2.3 Cautions on Problem Definition

The acronym CAPE is just an aid to formulating a definition so one should not worry whether something is a characteristic or an effect - that does not matter very much because the whole idea is to uncover problem aspects and expand one's understanding of the problem theme.

As a very rough guide one often finds that the final definition must come down to about a third of what we start with. In most cases if one is familiar with the subject it is possible to create a good definition in about 1 to 2 hours and then if necessary update it as your project progresses as it is almost certain that there are elements that have been missed or imperfectly understood.

6.2.4 Problem Size

It is hard to measure the "size" of a problem because there is no scale on which to gauge it. But one can look at two aspects to get some idea.

Current Effects – think about the effects of the existing problem and try to assess their seriousness in terms of the context in which it is set. In simple terms just ask "is it worth solving".

Form of Answer – perhaps a better guide is to think about the form of answer and see how extensive, important and how hard it is to get. For example: one student wanted to deal with password overload – a clear problem with which we are all familiar but his outcome was a set of guidelines on how to construct good passwords but in my view that was a trivial answer to the problem because those guidelines can be found almost anywhere and it is doubtful if that goes anyway to solving the overload problem.

6.3 Project Target

When you think of a problem you normally do it in relation to its effects. It follows that you have to think very early in a project about what effects will be generated if you can resolve the problem – these real world effects are called the project target. Normally one settles on one major target although it is permissible to list more than one. Targets are effects so these are typically introduced by a verb form (increase, reduce, remove, reduce etc) and tend to be such things as: improved accuracy in data entry, to gain infrastructure resilience, streamlined workflow and so on.

6.4 Project Outcome

It is obvious that at the start of a project we do not have its outcome – but we can have some idea what its form may be. Therefore if we know our target we can speculate about what could be generated as a project outcome that might generate or go some way to generating the desirable target. It follows that whatever we

decide is the form of outcome we are looking for in the MSc project it must credibly be able to generate the stated target. Outcomes are objects and so are typically expressed as nouns: Here are some examples:

The target of “improved accuracy in data entry” might be generated by a project outcome of a training needs assessment report or a training plan.

The target is “to gain infrastructure resilience” might be generated by a project outcome of a revised backbone design or a set of recommendations for new technology.

6.5 Problem, Theory (Speculation) and Form

It is often useful when thinking about the solution to a problem theme to think of it as based around or generated by some personal theory a person holds about that problem and its setting. Essentially, one gets at this theory by speculating about causes and possible solutions routes. It is not easy to say how to speculate but it can be said that it is aided by a thorough literature review, personal experience and a deep consideration of the problem theme perceived in a given situation.

For example suppose the situation was related to issues with application software implementations in business not being as successful as expected. Recognition of this problem theme is a first step but if one is to do something about it, it might be useful to thoughtfully speculate on why success is lacking in this area. It follows that one might speculate that this lack of implementation success is due to poor implementation strategies, or poor user training, or poor project management or any number of things. Notice that there will always be rival speculative ideas and that is why one must be thorough in looking at the literature and using your basic knowledge and experience to open up the situation in order to at least have a credible theory as to the most probable solution route otherwise one might just waste time on chasing nothing of value.

Do not let this idea run away – this is not about natural laws of the universe such as Ohms law or Archimedes Principle – here one tries to establish a personal belief about a situation and its problem theme. So after speculation one might express ones personal theory about the above example as follows.

It is believed that implementation of application software is proving difficult and this may be due to poor implementation strategies. It follows that if this is the case and better strategies can be defined then implementations may prove more useful in the future.

Notice that my theory points to a particular form of answer to this problem theme and in this case it is related to perhaps a document that explains how to formulate implementation strategies based on a consideration of user needs, application intention and business objectives.

Occasionally, the theory may be embodied in a scientifically constructed hypothesis but more often than not in technological research it is expressed informally as an idea.

6.6 Primary Data

Primary Data is data is new data in the sense that it will not exist as a collection until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data collection is representative of some aspect of the area under investigation and can be processed to get a defined form of outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

6.6.1 Primary Data Collection Protocol

Within every project there has to be a collection protocol for the practical collection of the primary data. Every complete protocol will have 5 features:

Vehicle – this is the primary mechanism or technique employed by the researcher, typical examples are: interview, questionnaire, observation, role playing, seminar, focus groups, document searching and so on

Recording Profile – this describes how the data will be physically recorded. Typically we might use: written report/transcripts, formatted record sheets, video, sound recording, computer logging, excerpts from documents and so on.

Sample criteria –this is a profile that allows the researcher to know that he/she has a valid sample point from which data is to be collected. For example, if we wanted data on business uses of Digital Paper we need a profile of who we should ask for that information. If we do not have a profile we may not have any consistency in our data and it may therefore be meaningless.

Permission – you have to feel certain that the information you seek is legitimately available to you.

Ethical Profile – you need to be clear as to what you are doing, the way you are doing it and what you are asking for is ethically acceptable. Two things are at stake: the results may be biased and the results may not be acceptable.

6.6.2 Project Purpose in a Nutshell

Students sometimes get confused over what a Master's project is about. Consider a topic area like Digital Paper which is likely to be a very hot technology in 2006/7. A Master's project is not about producing a long narrative on Digital Paper explaining what it is, how it is used and what the technological infrastructure to support it might be. A Master's project is about identifying a problem theme in Digital Paper and then collecting and processing primary data into a form that helps you resolve that problem theme based on ones own personal theory. With this in mind, consider the following examples.

Example 1. Suppose I want to define all the various accounting functions so I pick up a manual for my in-house accounting system and then go through it looking for all the various accounting functions and listing them – is that primary data and is this a valid research purpose? No because in the first place one might just regard the manual as listing the functions anyway so in effect the data already exists, secondly, this is just one book and so its content might be complex, trivial or totally unrepresentative.

Example 2. So if I extract (my basic activity) instances of phishing (my problem theme) from an email log that would be primary data because even though the email log (secondary data) obviously exists, the list of phishing instances (my primary data) as a collection did not. My purpose being to process this collection of primary data to find out the most common sources of phishing and express my findings in an evaluatory report (my form of answer).

Example 3. If I conduct interviews in order to describe (my basic activity) a user purpose regarding illegal downloads (my problem theme) in my company with selected employees the interview transcripts are my raw primary data because the transcripts did not exist before the interviews took place. My purpose being to process this collection of primary data in order to develop a policy (my form of answer) to control illegal downloading activity.

Example 4. If I look through written reports (secondary data) on security violations (my problem theme) for a particular company with a view to identifying (my basic activity) the root cause of each violation then even though the violation reports exist the list of root causes (my primary data) did not so it is primary data. My purpose being to process that collection of primary data to create a strategy (my form of answer) that will alleviate or remove certain kinds of violation in future.

Example 5. If I plan to build an application for processing student MSc marks (my problem theme) then I need to ascertain (my basic activity) the system requirements (my primary data). My purpose being to process this collection of primary data to create a design (my form of answer) for the marks processing system.

6.6.3 Pre-processing Primary Raw Data

In many cases it will be necessary to process the raw data that one collects into a structured form of some kind so that is easier to use when generating the final project outcome. For example, if we have a series of interview transcripts it is obvious, that in that form, they are not easy to use so we might perform a pre-processing phase to get the core data into more structured form that then constitutes our primary data collection before the main processing phase that generates my project outcome is carried out. For example, suppose I examine company documents on misuse of IT system resources by employees. In this case I might proceed in two ways to get my structured primary data collection.

In line processing – that is I define my structure before I start and then as I come across a misuse example I structure it there and then. However, the disadvantage here is that you have to continually look back to see that you are not recoding the same data again and again from other incidents and so it tends to disrupt the collection process and make it longer to complete.

Pre-processing – here I wait until I have been through all the documents and then I use my set of notes to systematically work through the whole raw collection and form my structured collection that way.

6.7 Writing a Research Question (Study Projects)

This is intended to relate to the core problem that your research is trying to resolve. Make sure it is a clear question. Ideally one wants an open question: that is one that does not just end with a yes or no answer. This is often quite difficult to achieve but it can be done if you work at it.

A question is an expressions normally used to request information the form of an answer. Questions can sometimes be like commands used to elicit a response and others such as "Would you pass the salt?" looks like a question but in fact is a request or action, not for an answer. In Research Methods, however we will only look for questions that elicit information.

The simplest questions implicitly or explicitly request information from a range (finite or infinite) of alternatives and these are often called bi-polar questions. An interrogative word is a word used to start a question. In English the following is a list of interrogative words although some of them are rather old fashioned now.

Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, is/are, and can.

6.7.1 Questions that are not Questions

It is often difficult to write something that in English could be taken as a question. Now I am sure that in daily life everyone knows how to ask a question but when you write something down you are entering another world. Consider the following two lines – would they be understood as proper questions?

How to sharpen a pencil? Or What a pencil can do for you as a student?

Now these clearly ask for information but if you spoke these fragments to someone they would not quite see it as a proper question – in English such fragments would be understood as a kind of heading to a list of instructions for sharpening a pencil or a list of the benefits of using a pencil.

6.7.2 Basic Research Question forms

It is best when attempting to construct a question to think about what sort of answer is to be expected – now in normal everyday life we do this instinctively. For example, you would not say "is this the right way to Pablo's restaurant" if you wanted actual directions because that question form could only give you a Y/N answer. Instead you would probably say something like "how do I get to Pablo's restaurant from here" and reasonably you would expect an explanation to that question. Broadly speaking there are four sorts of answer:

Bi-polar answers - Essentially questions that imply a limited range of possible answers. Typically, a bi-polar question starts with a word such as WHAT, IS, CAN or DOES.

Is it possible to sharpen this pencil? (Y/N)
Does it make sense to allow children to sharpen pencils (Y/N)
Can a blue pencil be sharpened easily (Y/N)
What is the correct pencil weight for drawing a picture? (HB1, HB2 etc)
What is the common view of staff about using blue pencils? (Disagree, agree, etc)

Bi-polar questions can of course be useful but more often than not they have no great utility and the answer is obviously yes or no. Consider the question: "Can a green pencil be used in place of a red one?" Well of course it "can" be used so the answer is bound to be YES and so the question is pointless. Sadly, questions in this form occur all too frequently in student work and whoever writes such questions is not thinking at all about what information he/she want to elicit.

Explanatory answers – where the expected answer is an explanation and it is often in the form of a procedure or process. Typically, explanatory questions that start with 'HOW' or 'WHY'. For example, "How can a pencil be sharpened safely by young children?"

Descriptive answers – where the expected form of answer is a description most often in the form of an evaluation. Typically, these questions start with WHAT or WHY. For example, "What is the purpose of HB0 pencils?" (a simple explanation) or "Why are HB0 pencils difficult to sharpen?" (an evaluation)

Exploratory answers – where the expected form of answer implies an answer as an exploration of something. Typically, exploratory questions start with HOW or WHY. For example, "How should we use HB1 pencils best in drawing figures?" (often an exploration is needed here leading to an explanation)

Good interrogative words to start questions are: what, where, would, in what way, can, is it, why, which, where, how, does, who, why, do, etc – whatever word you use always ask what form of answer is implied by each of them. You must be sure that whatever form you decide on as answer that you can actually construct it and when it is constructed as part of your research it is in fact useful strategically in some way.

For example, suppose I decide that the form of answer I want is “The role of technological innovation is business success”. Well the task you now have is to now ask yourself whether you know how to express a role (write it down if you like) and whether knowing about this role will be of any use.

6.7.3 Research Question – Why are we asking it?

In normal everyday life questions come at us more or less all the time. Sometime we just answer them but more often that not we have a tendency to ask “why do you want to know”? It is therefore always useful when setting out your research question to ask why you asking it. That is you say to yourself, if I have the answer to this question then there will be some good outcome because of it. Sometimes we embed in our questions why we are asking them but mostly we do not. You will see later however, that you will have to make the reason plain in the aim so one might as well think it through at the question stage as well.

6.7.4 Research Question Form of Answer

For any Research Question there will always be several possible forms of answer arising out of ones personal theory about a problem situation encapsulated in the question. Ideally one would like the research question to be worded so that ONLY one form answer is possible and that is the one our theory suggested but often that is not easy to do so one normally has a range of options and competing theories to choose from so one looks for a form that interests you or looks to have the most utility. Do not be tempted to have multiple questions all in one sentence or look for multiple answers since it is better to focus on one significant output form. Table 4 lists the main forms of answer to help you when considering your personal theory.

Category	Typical Interrogatives	Expected Forms
Bi-polar	does, is, are, what, when or can	A list of possibilities
Explanations	how, why, who or where	A report, a model, an equation, a theory, a design, an evaluation etc
Explorations	How, who or what	A list, explanation, a comparison matrix, a pattern, a survey report, a theory etc
Descriptions	What, who or why	A report, a process or procedure, a model, a policy, a strategy, a theory etc
Table 5. Research Question Outcome Possibilities		

6.7.5 Strategy for formulating a Research Question

There is no easy way to do this and no real templates for it either so a good formulation will require some clear thinking and effort. What follows is a typical structure that you might use, but do not feel limited by it. The order in which these structural elements are presented is usually IPSTS but do not worry too much about this as long as your question is lucid but on the other hand do not be careless and end up with a question about the suggested outcome instead of about the problem (**SPITS** for short)

Spotlight – try to put the spotlight on where the primary data or information needed to answer the question might help come from.

Problem – this is about focusing on a single problem, so try to be as concise as you can.

Interrogative – what is your key interrogative word (how, why, what etc). You should note that some interrogatives need to use two words if a proper question is to be formed. For example, “how” on its own will not normally make a question but when you say “how can..” it is clearly a question.

Target – think about what will happen in the real world if you can resolve the problem. For example, it might be your target was to gain efficiency improvements, provide or enable better communication, increased accuracy and so on. It is also possible, but usually unwise, to state the target negatively if this makes the wording of the question more natural and you will see examples of this in section 6.7.

Suggestion – here one thinks about the problem theme and simply asks what sort of answer and what form it might take. So sort of answer might be yes/no, an explanation, an exploration, a description and these sorts of answer might be expressed at the end of the project as a report, a model, a list and so on.

Here is a student work example - "How can (interrogative) the billing cycle time (problem) be reduced by identifying and defining best practice accounting (suggested outcome) in order to improve the quality of response (target) to customers by reviewing the initial accounting processes stages (spotlight)?"

It is not always useful to add in the data suggested outcome because sometimes it can limit ones speculation about causes and solutions and in any case.

6.7.6 Function of a Research Question

The function of the research question is to crystallise the problem and desired effect (target) of any solution. But doing this is only useful if it allows the research enough room to theorise or speculate about possible answers so that indeed the solution space can be explored. Consider the following formulation:

"What factors influences the development of sound IT project management working relationships?"

Here we have in a solution because we are told that the problem is "working relationships" and what we want as a target is sound working relationships. But we in effect we are told to look for factors and so the solution to this problem theme will be a list of factors. The trouble with doing this is that it cuts off any further speculation about dealing with this problem idea and so the question becomes rather pointless.

6.7.7 Meaning in a Research Question

This section has looked at the structure of a typical Research Question but that is all it is and students must not treat it as some sort of template – it MUST be thought out step by step and even then one has to think does it make any sense, is it a focused question, what sort of answer should I expect and so on – there is simply no substitute for careful thinking.

Once you have formulated your research question and have a good idea what form the answer will take then its time to test it using the following ideas. Now be aware that this is just a test of structure and of itself it does not mean the question makes sense – there is no way to do that other than using your own brainpower and common sense – if it makes sense to you it will probably make sense to whoever else looks at it.

English – does it read correctly in English as a question?

Paraphrase – if it's a good question you may be able to ask it in several different ways – so try to do that until you get a formulation you are happy with.

Bi-polar – this means that the question has a fixed and limited range of answers such as "Y/N", "bad", "good", and "excellent". This type of question can of course be useful but the problem with them is that such answers do not have much utility – that is they do not tell you anything of value in terms of what action or actions you might take. You are advised to avoid such questions for your project.

Discussion – look at your question and honestly ask 'will this question produce discussion?' – what this means is to ask 'who am I writing this question for and would it interest them'. Try not to think that you are doing this for your Research Methods tutor but try to think what you would do if you were trying to get funding for research to get an answer to the question from someone.

Answer Form – try to work out what form or forms the answer will take (typically: bi-polar, explanation, description or an exploration) – if you try to avoid this aspect you may find yourself in serious trouble with your research.

6.7.8 Common Errors in Research Questions

The following are typical errors found in student written Research Questions – they can all be avoided if one takes just a minute to think through what has been asked and what sort of answer is likely.

Not a Question - to an English speaker the following would not sound like a question, instead it would sound like a heading to a list of instructions or a procedure. "How to make business application development productive at XYZ Corporation?"

Multiple Questions – It is never a good idea to try to put TWO (or more) questions into one as in the following example - one is about testing and one is about bugs they are quite different things. "How can software bugs be minimised and the testing cycle shortened in the development process of an Inventory System?"

Obvious Answer – these are cases when no research is needed because the answer is either obvious or common knowledge. Questions like this show a serious lack of thought – take the second example and it is easy to see that the answer to the question is bound to be YES - of course a productive work-life balance "CAN" (but might not) be obtained so there is nothing of any value whatsoever in a question like this. Similarly, it is easy to explain how a better development process can increase productivity.

"How can a better business application development process increase the productivity at XYZ?" or

"Can a productive work-life balance be achieved with telecommuting for technical personnel?"

Please remember that it is possible to write a very poor question that exhibits more than just one error type. Again, there is simply no substitute for thinking about what it is you have written.

6.8 Primary Data Generation with BAGeD

Based on a problem theme, theory and the form of the project outcome expected one needs to formulate a process to create a unified collection of primary data. There is no algorithm for doing this and one has to go carefully through the steps: define the data (BAGeD), locate the data and decide on a protocol to collect that data reliably.

Spotlight - The core of this primary data generation process is to find an activity whose execution effectively points to the right data so that you can formulate the whole collection plan around that activity. This core activity is called a Basic Activity for Generating Data (acronym BAGeD) and is the activity that one performs to generate the primary data that you want. Think of the BAGeD as a sort of spotlight that is focused just on the primary data that one needs and nothing else. That is the spotlight illuminates the data that you want in the sense it tells you how to generate primary data items but not how to actually collect that data.

With a BAGeD it is ideal if you can find just one verb to describe the activity. One needs to be careful here that the activity is clear since almost all verbs need to be qualified or supported by stating what the object of the activity is. For example, if I were to say, "look at fault logs for my primary data" then that is very indistinct because it does not tell us what to look for (the object of the looking). But if I say, "look at fault logs to describe instances of SPAM attacks" then I now have a more distinct activity because I know what I am going to write down as my primary data. The whole primary data collection process is then fitted around the BAGeD and the detailed planning to get the necessary data can then be made.

Example - suppose the problem theme is the value of training. Clearly a lot of money is spent on training so it might be really useful to know if there is a link between it and productivity. Suppose we speculate that the link is to do with essential business working practices and these change over time to meet new needs so that what I need is an answer in the form of a process model on how one identifies changes in business essential working practices and links them to a training initiative.

Now that I have my theory and form of answer (a process model) the Basic Activity for Generating Data can become **describe changes in essential working practices** of key operational staff – thus, my Basic Activity is "**describe**" and the Primary Data will be **changes in essential working practices**. In practice you might try several ideas before you are happy with one. Now I have this core activity I can work out the full process of getting to the data and processing the resultant collection to get my process model (outcome) that describes the link between business essential working practices and training.

Once the BAGeD is clear it, is an easy step to say how that data will be collected. In the above example I might use interviews with relevant staff. In summary the whole process becomes **describe changes in essential working practices** (BAGeD) using **interviewing** (collection protocol) with relevant staff.

6.9 Getting a BAGeD

The Basic Activity for Generating Data (BAGeD) then is an idea that allows you to spotlight exactly the data that you want. So we are looking for an activity and we hope that activity will shine a spotlight on the data. There are only three real considerations:

Problem Area Expertise – it is obvious that you need to have gained expert knowledge in the topic area and in the particular aspect related to the problem theme you are dealing with. In general, depending on the topic, this might include things such as: knowledge of the technology, management and usage processes. Unless you have thoroughly prepared by using literature reviews and/or other means you will simply not be in a position to know enough to be able to decide competently what data it is possible to collect.

Intended Outcome – fix in your mind what your Research Design is trying to generate as an outcome. With the above in mind, recall that whatever data you collect will be first formed into a structured primary data collection during the pre-processing phase, which follows immediately after collection, and then that structured collection will be used to generate your outcome.

Let us suppose the outcome is to be a set of guidelines, so you have to think what sort of primary data is needed to be able to generate the guidelines. This means you must know what guideline means and how one is constructed and that is where secondary data comes in. So in this case you might look at text books or journal articles to find a guideline model to use. Additionally, you would look at examples as well as look at any relevant company or international standards.

Collection Protocol – the last thing to consider is can the data be collected and if it so, what is the best way to do that. So it's not a matter of just choosing anything that comes to hand, it is a serious practical consideration based on a thorough and logical analysis of the sort of primary data that you want.

In the guidelines example above, the idea might be to use a questionnaire and one has to ask would a questionnaire allow for the collection of the data I needed. Let us suppose that the data we spotlight is: IT media and usage. Now it's obvious that a questionnaire can easily get media data but it is not clear how it could capture usage data so I might decide to get that information by interview instead because I want a much richer picture there. The point is that guidelines are largely about usage so that is where I must direct my effort.

To elaborate, usage is a complex issue and if you try to get it with a questionnaire you are going to have to have a very good idea what the usage processes are and so it may miss lots of things that are going on in the company setting. Whereas, if I use an interview, I have much more opportunity to explore the usage idea and that is what I really want.

6.10 Research Question, Form of Answer and BAGeD Examples

Consider the following further examples which focus on the BAGeD (your data spotlight) and linking it with some theorising or speculation about an expected form of answer. In each case several possible forms of answer are listed but in a research study only one would be chosen for further work.

One needs to be careful – this all sounds fine, even clever but a researcher must seriously consider if a complete process built around the BAGeD can be formulated in order to get at the necessary data within the time and other resources that are available.

RQ = What limits investment into e-applications for SMEs in Hong Kong leading to a loss of competitiveness?

- A list and description of investment constraints or
- A strategy to deal with the investment constraints or
- A feasibility report on e-application implementation or
- A post implementation review report or
- A prediction reacted to the effects of the constraints

Let us suppose that I choose a list and description as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on reviewing investment plans and the corresponding strategic plan in order to identify (Basic Activity) the possibility of an investment constraint (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to collect investment and strategic plans (secondary data) and by a process of review I identify and extract key investment decisions in the investment plan linked to a strategic plan. So my primary data will consist of a list of identified investment constraints, which I will need to explain.

RQ = How can IT operational criticality be monitored and controlled in order to build effective business systems?

- A process of data criticality categorisations or
- A user guide to data criticality or
- A DRP/BCP policy document or
- A report explaining how data and criticality are related

Let us suppose that I choose a DRP/BCP policy document my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on listing data categories and using these categories I review reported critical incidents related to data categories in order to match (Basic Activity) the category to the criticality of the incident (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to collect category

data (secondary since they must exist in this case) and collect incident reports (secondary data) and by a process of evaluation of each report extract incident details and categorise them (my primary data). So my primary data will consist of a list of categorised critical incidents.

RQ = How can supply chain logistics be improved to provide continuity in manufacturing systems?

- A evaluation of a modern supply change process or
- A feasibility report on RFID or
- An implementation plan for RFID or
- A model that shows how improvements may be made using RFID

Let us suppose that I choose a list of implied benefits all explained as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on describing (Basic Activity) supply chain tracking problem themes (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to identify tracking problem themes and by process of evaluation of each problem theme I analyse how RFID might alleviate that problem theme. In essence I extract key reported problem themes and possibly categorise them (my primary data). So my primary data will consist of a list of categorised problem themes in supply chain tracking.

RQ = How can an improved personal communication protocols be established leading to productivity and business success?

- A feasibility study on IM and its use in offices or
- The definition of a training programme or
- A series of factors that must be in place before IM adoption or
- A cost/benefits report or
- The design of a regular monitoring scheme to assess effectiveness

Let us suppose that I choose a cost/benefit report as my expected form of answer. Now I have to find a way of getting at the data I need – the Basic Activity for Generating Data. So I decide to focus on analysing (Basic Activity) call content with regard to costs (Generated Primary Data). Now I can see more clearly what my data is going to be. Here I need to identify the sort or calls and then extract the cost (easy) and assess the benefit (hard) and by process of evaluation arrive at my report. So my primary data will consist of a list of calls and their associated cost and benefit.

6.11 Writing an Hypothesis

This matches with your research question and amounts to you saying what you think to be true in a given situation. It is in essence an extension of your form of answer where you try to say not only the form but what you think the answer will actually be. When you do this your work then become a process whereby you try to show that your hypothesis is valid. It is quite difficult to write a suitable hypothesis. There are three stages: firstly write the null hypothesis, secondly write the alternative hypothesis and lastly write down the dependant and independent variables. Unfortunately many new researchers seem unable to do these things satisfactorily. Let me illustrate.

A student wanted to write a hypothesis that essentially said that there was a link between IT certification training and personal productivity in support roles. He then went on to define the variables as: Role of IT (independent) and Personal Productivity (Dependent). Now this will ONLY makes sense if you can quantify the variables productivity (which is quite easy) and 'Role of IT' which it seems cannot be quantified. Now in research people tend to treat the idea of hypothesis in two ways and the second way is often quite valuable in many research situations.

6.11.1 Formal Experiment

To set up a formal experiment one creates or identifies two samples: one exposed to some effect and one not. For example, suppose I were looking at whether a new diet called lose-weight-quick worked or not. I could set it up a hypothesis and look for samples where some people were exposed to the new diet and some were who were not. The experiment then amounts to seeing if there is any significant difference between these two samples. (See notes for how to set up a formal hypothesis)

In a sense we are trying to prove the diet works but that notion of proof needs very careful understanding. The point is that it is very likely that the diet will work for many in the sample and not work for others. So our proof carries a qualification which is that all we could reasonably say at the end is that the diet is likely to work for a large number of people (or not as the case may be). A second point is that we do not usually do thousands of similar experiments and so at best our results for a limited sample would be tentative. Notice

that this outcome is quite different from an experiment that sets out to verify a natural law like Archimedes principle or Ohms law where the amount of variety is much, much less and of course such natural laws have been tested many thousands of times so we are assured of their validity.

6.11.2 Informal Idea

Instead we could just have what might be called a tentative hypothesis that suggests that there may be a link and then use case studies to demonstrate this. Notice that we are NOT proving anything here only suggesting that something may be true.

6.12 Writing an Aim and Objectives

For each project we want one overall aim and a set of objectives that collectively will generate the form of answer that has been defined (project outcome). An aim/objective is expressed as an activity to get to a defined and measurable outcome within the scope of the project. The essential difference is that the aim expresses the target (or purpose) for the whole project outcome whilst objectives perform the same function within the project itself. Every time you write an aim or and objective you have to ask three main things with the abbreviation JOB – so when you write an aim or objective make sure you do a good JOB of it.

Can Justify – this really amounts to asking if the aim/objective make sense in that it generates a minor project outcome within a particular aim.

Can Observe - Make sure than someone else can observe or check what you have done, normally this means you can document it in some way (in words, diagrams, charts, graphs etc) in your project document. For Engineering projects this also means that the application is visible to all markers.

Can Build - Make sure that YOU can build the outcome stated.

6.12.1 Project Aim

This derives from the project problem definition and is best thought of as expressing the overall activity and intention of the project to generate an outcome that can be placed in the project document or made easily visible to the examiners. It has a number of elements as follows although when you write your aim you do not have to do it in the same sequences as expressed here and you may write it in any way that best captures your ideas although doing it in this sequence tends to be more logical.

You will note in the aim structure that follows that the problem theme is not explicitly mentioned and we infer what it is by looking at the target. The reason it is not included explicitly is that when one does one tends to get very awkward constructions linking problem and target so we might see absurdities such as “to improve website accessibility because web site accessibility is problematic”. The structure of a good aim is as follows where we can use the acronym ASOT to remember it.

Activity – what must be done with the available data to get the project outcome? Ideally, look for a single activity that sums up the whole project process for generating the intended outcome.

Spotlight – where will the basic data used by the activity come from?

Outcome – this element says how the project outcome will be expressed knowing that this outcome will later be used to generate the real world target. If the Research Question expects a model as an answer then the aim must have the same form of generating the model. Similarly, if the application description states a system to do X then the aim must have the intention of generating system X.

Target – what is the real world intention? That is the project outcome should be useful in the sense that it addresses the real world problem theme on which the project is based.

Aim – to create a website structure design using cascading style sheets in order that it might be used in design to improve web site accessibility.

Activity = create, **Spotlight** = cascading style sheets, **outcome** = web site structure design and

Target = to improve accessibility.

Sample Aim 1 – “To create an improved network infrastructure”. This is unsatisfactory because we have no target - we know that there will be an improved infrastructure but we don't know what effects that will have. So is improved infrastructure the outcome – it cannot be because it would imply sending to Portsmouth for marking some object called “improved infrastructure” and that is an absurdity. So here we

have no target and no outcome and we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

So if I just use the above example it would be possible to have a target of a reduced network down time because of the Improved network infrastructure but that could ONLY happen after the project completes and in the project one could generate an infrastructure design - now that can be completed within the project period and later used to build the infrastructure which can then be used to generate our reduced network down time. Another factor here is that we cannot measure whether something called improved network infrastructure (what scale would we use?) has been achieved unless we have a target such as reduced down time which of course we can measure.

Sample Aim 2 – “To build a Wi-Fi implementation strategy”. This is unsatisfactory because although we know the project outcome is an implementation strategy we do not know what value it has in the real world because we have no target. Notice also we are not given any spotlight area for the work so we have no idea what will be used to get to the project outcome.

6.12.2 Project Objectives

The aim expresses the overall outcome for the project but to get there we normally have to pass through a number of minor outcomes on the way and these are expressed as being generated by objectives. For example, an objective that sets out to build a model of the software construction process could easily be a minor outcome for a project dealing with the construction of web sites but could also stand on its own in the sense that it is a useful outcome whether the project is completed or not. Conversely the design of a set of interview questions is most likely not to be an objective but a simple project task since it is something that needs to be done but only has meaning within the project.

Since we are looking for minor project outcomes that collectively deliver the project outcome we have a little problem here because any project is made up of a series of tasks, some of which will generate a minor project outcome and some will not. For example project tasks range from preparing the contents list to evaluating the project outcome. A possible rule for deciding if a task leads to an objective is:

Ask is the object produced by the task something that could stand on its own outside the project and in that sense valuable in its own right?

If the answer to the first is “Yes” then it is likely to be a task that leads to an objective. Please take care; this is just a “rule of thumb” so look for things as minor outcome that are real milestones to getting the project finished. It may be useful to think of the project as a pyramid where the final project outcome is at the top and below it are layers that have been generated progressively from objective minor outcomes so that we eventually get to the top.

The format for an objective is much the same as for an aim but with no target and two added features in that they must be progressive and bounded. There is only one aim but there may be from 3 to 6 objectives that show a progression that leads us to the overall project outcome.

Progressive – objectives must build sequentially so that collectively they amount to reaching the aim.

Activity – Ideally we look for a single activity that will generate a minor project outcome that can be expressed in a form that can appear in the project document

Spotlight – what is the data area focus of the objective's activity?

Outcome – In this element you say how the outcome of your objective will be expressed knowing that this must be in a form that can be written into the project document.

Bounded - objective outcomes must be achieved and available within the project period and must not refer to anything that might occur after the project document is completed and submitted

Example – To model and document the software development process.

Activity = model, **Spotlight** = software development process, **Outcome** = a document, Bounded – yes we can do this activity within the project period (in this case we cannot show progression as that only applies to the complete collection of objectives)

It is easy to become completely muddled with objectives and one source of this muddle is the distinction between a project objective: one about what a student can do and evidence in the project document and operational ones: those that have some real world effect that might happen after the project has been completed. In simple terms if you set an objective in your project it must be completed within the projects time scale. Let us just take an aim and look at some possible objectives.

Aim = To report on how the bicycle is an aid to mobility in a modern urban environment

Sample Objective 1 – “To list in a report the components of a modern bicycle”. This is fine since clearly it is something that you can do and evidence in a project document so somebody else could check what you have done.

Sample Objective 2 – “To describe how a bicycle functions”. This is no good since although it is clear that you can develop a description, no one can check it unless you write it down. Better to say “To describe by means of annotated diagrams how a bicycle functions”

Sample Objective 3 – “To understand how a bicycle helps urban workers”. This is no good because although you can do it no one else can check it. Better to say, “To prepare a report explaining how urban workers could be helped by the use of a bicycle”.

Sample Objective 4 - “To ensure that workers get to their office on time by using a bicycle”. This is no good because you cannot do it and if you cannot do it no one can check what you have done. It also sounds more like an aim than an objective because it hints at a target. Better to say “To report on bicycle usage strategies that might be applied by urban workers to ensure they get to work on time”.

Sample Objective 5 – “To implement a bicycle repair system”. This is no good since you can clearly do it but it cannot be checked in your project document. But you could say “Report on the implementation of a bicycle repair system” or “Produce a design document for the creation of a bicycle repair centre”.

Sample Objective 6 – “To ensure that bicycles conform to BS 7898”. This is not really much good as it is in essence a requirement and not something that one can do within a project itself. However, one might have written “To prepare a report showing how a bicycle can be evaluated for BS 7898 compliance”.

6.13 Words needing care in Aims, Objectives or Research Questions

The key thing is to look at the main verb (activity) you are using and ask ‘does it tell me what to do as a practice’, if not then its use is suspect. A good way to assess if the verb is strong enough is to connect it with an outcome. So we might write ‘Create a framework...’ – here we have the activity ‘create’ and the ‘outcome’ a ‘framework’ and it is easy to see that it can be done.

6.14 Writing a Title

The title is the name of your project – rather like the name of a novel, something that catches a potential reader’s attention but just gives a hint as to what the work is all about. Think of it as a kind of nickname or slogan for your project and as such it is not a good idea to try to use the same set of words for the title, Research Question and aim. Titles typically have two elements:

Aspect – this is the particular focused area of your study

Why – this says why it might be a useful aspect

Mentioning the means by which you solved your problem should only be included in the title if it is crucially important. As an example, suppose your project was concerned with the development of a database and you used Microsoft Access. Unless your project compared your product with a similar database implemented in Oracle, say, then the tool you used to solve the problem is not as important as the problem you set out to solve.

Be careful with titles, there is a tendency to use the title to say what you will do. The purpose of the title is to give a concise name to what you do. Avoid noise words or phrases such as: “A report into...” (redundant: of course it is a report!) or words like “study”, “investigation”, “enquiry” and “development” are often similarly just noise. It is also usually very unwise to express the title of your project as a question although a title in the form of a proposition is often quite useful as in example 1 below. Here are some examples of good titles:

Planar Similarity – A Possible Software Quality Measure
Heuristics in the Stages of Soft Systems Methodology
A Taxonomy of Heuristic Problem Solving

7. WORKBOOK 7 – BASIC RESEARCH METHODS CHECKLIST

In research we are usually trying to do one or more of the following: understand something, explore something, describe something, explain something, improve something, build something or prove something. To do any of the above, you will have to decide what data you want to collect and choose rationally a research method as your primary research vehicle and build a research design around it.

You need to exercise care here so as not to become confused between a Research Method, which is a framework or model for the whole research project, and Data Collection Protocols, which are vehicles for actually collecting the primary data and might include such things as interview, observation, questionnaire, seminar or role playing.

What follows is just a summary of the methods and further information can be found in the associate project notes and there are many books available on each of the methods listed below. There are many research methods but the list below presents the major ones.

7.1 Research Styles

This is a practical notion and you would be wise to think project ideas through in terms of these styles. There is no sense that one or other is superior and no reason why both should not be applied at the same time.

Quantitative – a style that represents information in numerical form. The numerical form might be graphs and statistics which can be used to show trends, comparison and similarities and the graphs might lead to equations which link variables or allow one to make generalisations.

The advantage of quantitative data is that there is solid evidence that can be permuted in a variety of ways to support or not support a contention. In general, one is counting the frequency of some event – say the number of times the user selects the wrong icon but, and it's a big but, the data is only truly valid in the context in which it was collected so one needs extreme care if we want to generalise.

Qualitative – is typically used to analyse how certain actions occur not just how often they occur. The information is usually represented in textual form of some kind as a description of some observable event or events. The usefulness of this is that it exposes the thought processes or reasoning behind a particular behaviour – why a user clicked the wrong icon. However, it does make the analysis and representation of the data more complex.

Although these are defined, in practice one does not usually start by thinking about the style and typically as you think about the problem and what primary data your research will collect to deal with it then it tends to define itself as predominantly quantitative or qualitative.

7.2 Research Approaches

There are two broad approaches to research, which is always essentially exploratory. In practice you do not decide the approach as such and it will effectively be decided for you when you formulate your research problem and construct your research design. However, we may loosely define:

Deductive – in the sense that we have a theory that we want to prove – in simple terms deduction amounts to a valid argument – that is if its premises are true then the conclusion automatically follows. Typically we form what is known as a null hypothesis. That is we set up our research question in the form that there is no effect of some parameter. For example, I might want to look at the significance of scripting languages on system development time. I could do this by setting up a null hypothesis that says 'I contend that the use of scripting languages have no effect on system development time'.

Inductive – in the sense that one hopes that the theory emerges from the data analysis as we go along. It follows that we don't have a hypothesis we just know that we want to explore a certain domain to see what emerges. For example, I might want to investigate the fact that students are not attending chat sessions but I have no idea why (I don't have a theory) so the whole point of doing the research is to explore the issue implied by the question and hope that something will emerge as I go along. So induction is a kind of grounded argument, the truth of whose individual premises would not *guarantee* the truth of its conclusion, yet one hopes that it would provide some evidence for it.

In short we might say that deduction is an outlook we take when we are sure that we know what the outcome is going to be but Induction is an outlook we take when we can only feel probable about a given outcome.

7.3 Research Outlook

Before we look at the various research methods it is useful just to records that there are two approaches that are available to a researchers.

Hypothesis Driven – this is the classical research paradigm where we have by some means devised a theory or speculation of some kind and the research is then directed at trying to show that the theory or speculation is valid. For example, we might theorise about who buys Gel Pens and then try to show that it is true, or more usefully try to explain in a report why it is true

Data Driven – it often happens that when we embark on research we don't have a hypothesis which we are setting out to test. This is very common today where corporations have vast databases and want to see if there is anything useful in there that might for example lead to competitive advantage. It follows, that in these cases we don't start with a hypothesis but we examine the data sets looking for patterns or outliers or indeed anything that might allows is to formulate a theory of some kind. For example, we might look through millions of sales transactions and then to hypothesise that people who buy Gel Pens all have beards and wear glasses. If this theory is true we can better target our Gel Pen products.

7.4 Which Method to Use?

There are many methods/models that we can use for setting up a research idea, the most common being: case studies, vignettes, action research, experiments, quasi-Experiments, surveys, biographies/histories, grounded theory, ethnography and requirements gathering. It is never easy to decide on a method or perhaps more than one method, but the following may help you to make up your mind. Start by asking what exactly are you trying to do or find out? This will help you decide whether you need a qualitative or quantitative approach. So here are something you might consider:

Choosing a method will depend on many factors such as: context, available literature base, basic research purpose, is the domain changing rapidly, time available, skill available, sampling and other practicalities, access, your personal stylistic inclinations, reason for the study, what kind of outcome you want, cost, quantitative/qualitative, scale, control, sensitivity of the data and so on. Notice these factors are almost all about practical things - the whole point being that a design has to be carried out and that means it has to be practical.

7.5 Research Basic Purpose

In research, usually we try to do one or more of the following: understand something, explore something, describe something, explain something, illustrate something, improve something, build something or prove something. It is therefore very important when you are trying to decide on a method to keep this basic purpose uppermost in your mind.

7.6 Rationale: Case Studies

The case study method focuses on just one, two or twenty examples – such as your place of work, or one element of your organization or several aspects of a problem area. Typically:

1. Case studies are commonly used to **illustrate** or **understand** a problem or **indicate** good practice.
2. Case studies always have a context so make sure you are aware of it.
3. Case studies are usually qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain or describe some activity or phenomena.
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. There are broadly speaking two ways to begin case studies. This first is that you can set criteria and then go looking for relevant cases or secondly you can design and create the cases.
7. For most case studies there is usually be a longitudinal element - that is the cases will run over a fixed time period and you will periodically visit each case to collect the data.
8. There are several kinds of case possible:

Unique – implying that the setting and context are extremely rare and there may no be another chance to study this problem area again.

Critical – implies an important theory that you want to test and a particular case fits that profile.

Representative – implies that the case profile represents a typical or everyday situation.

Revelatory – implies that the case profile allows a researcher to study a situation never before looked at in detail and its context may be come common.

9. In practice you can use the following to organise your cases but remember once you have your case design you will need permission from whoever is necessary.

How many cases – be practical because there are time limits.

Case Criteria - add as many criteria as you think necessary to pin down the data location but don't have so many that you will never find a case that fits.

Sample criteria (collection protocol) – add as many criteria as you need to pin down a particular sample point where a unit of data can be obtained.

Visit Frequency - each case must be visited to get the data so work this out by looking at how much total time is available for the study.

Data collection Vehicle – by observation, interview, document analysis, etc. You will have to have a protocol to say when a valid sample arrives.

7.7 Rationale: Vignettes

These are perhaps best thought of as micro case studies or snapshots that illustrate just one idea and almost always are qualitative in their application. Typically:

1. Vignettes are commonly used in research contexts where actions, motives and judgements are to be explored, often in sensitive situations and you want to extract and **describe** examples or **illustrations** of significant elements in that problem domain
2. Vignettes always have a context so make sure you are aware of it.
3. Vignettes are essentially qualitative in nature.
4. Typically indicated as useful when the research question starts with 'how' or 'why' and there is a desire to explain, test an idea or describe some activity or phenomena.
5. Typically you cannot control and indeed have no desire to control the events being looked at but the events should be contemporary.
6. Vignettes enable participants to define the situation in their own terms or for their needs.
7. Most vignettes are "one off" events and as such act as indicators of an idea rather than as some sort of proof of concept. Therefore, this may also be useful when only a small sample is possible.

7.8 Rationale: Action Research

The main purpose of action research is to improve identified practice in some way. Typically:

1. Action research is commonly used to conduct research at the workplace with a strong desire to **improving** aspects of your own or colleagues' work so
2. In this kind of research you must be in control of events and they must be contemporary.
3. Typically indicated as useful when the research question starts with 'how' and there is a desire to explain something and use that explanation to improve practice.
4. Because of its setting, it is obvious that the research design is linked closely to its context.
5. The whole point of doing action research is the research leads to change in practice.
6. The working strategy is: plan something, do something, observe the something and reflect on what has happened as a result of your actions.

7.9 Rationale: Experiments

This form of research is used where there is a hypothesis and an associated variable that you can control (the independent variable) that will produce a change in some other variable (the dependent variable). That is the whole idea implies that you can intervene by altering or controlling the independent variable. Typically:

1. Experiments are commonly used when you want to **prove** or at least **indicate** that something is true. In practice proof is very difficult as it would imply that your findings are true for everyone, everywhere and for all time and so then tendency is to say indicate rather than prove in most cases.
2. In very simple terms one forms two groups: one which is exposed to the intervention and one which is not and then we observe if there is any difference because of the intervention.
3. Typically indicated when the research question starts with 'how' or 'why'.
4. The researchers must be in control of the events being looked at and they must be contemporary.
5. The biggest risk is that there may be other variables involved which we are not aware of.
6. It is difficult to be sure that our sample is representative.

7.10 Rationale: Quasi-Experiments

This form of research is used where there is a hypothesis and associated variables but you cannot control any of them. It would be nice to think we always had time and resources to run a carefully designed experiment but unfortunately this is often not the case. In an experimental design one chooses the samples involved randomly and thus one has control. However, it may be that data already exists and you can test your theory on that existing data or it may be that you simply cannot get control over all the variables that you want. So an experiment and a quasi-experiment are very similar it's just that the quasi-experiment does not quite have all the trappings that a full experiment has.

7.11 Rationale: Surveys

This form of research is used when we want to ask a group of people a question or questions. Typically:

1. Surveys are commonly used when one needs to get and express an overall **understanding** of the properties in a given domain.
2. One could of course also survey 'things' as well as people.
3. Surveys lend themselves to future replication.
4. Typically indicated when the research question starts with 'who', 'what', 'where', 'how' many' and 'how much'
5. There is no need for you to control the events being looked at but the events should be contemporary.
6. Questions must be well-designed and unbiased and may be asked by interview or questionnaire.
7. Be careful to distinguish questions that are asking for facts and questions that are asking for opinion
8. The results will be very dependant on having a big enough and representative sample.
9. Be clear as to how the data will be collected – by observation, interview, questionnaire, etc. You will have to have a protocol to say when a valid sample arrives.

7.12 Rationale: Biographies/History

This form of research is used when we want to trace an historical event and analyses/evaluate its history as this may lead to insights or explain certain action so that lessons may be learned.

1. Biographies/History are commonly used to form a **description** and **explanation** of events.
2. One can use this to look at individuals or organisations or even technology.
3. Typically indicated when the research question starts with 'what'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. Be clear as to how the data will be collected – by documentary study and interviews are common.
7. Histories are naturally chronological and are characterised by epiphanies (pivotal events) and almost always exists in a context.

7.13 Rationale: Grounded Theory

Here the main idea is to use research to arrive at a theory based (grounded) on collected data. Grounded theory is quite difficult to understand and practice.

1. Grounded theory is used in situation where the theory is unclear or even unknown and so there is a need to **explore** seeking **description** and **explanations** in a domain.
2. One can use this to look at organisations or technology.
3. Typically indicated when the research question starts with 'why'.
4. You cannot control the events being looked at but the events need not be contemporary.
5. This is typically a qualitative study.
6. Be clear as to how the data will be collected – by documentary study, interviews, questionnaires etc.
7. Grounded theory is systematic in that the idea is to gradually move closer to a position where we can suggest a theory or proposition.
8. The basic unit of research is the category which is something that may represent a unit of information and might be almost anything.
9. The essence of grounded theory is in its data processing where various forms of coding are used to gradually unlock meaning in the data.

Open Coding – essentially the formation of the initial categories of information – it is characterised by looking for properties or asking when the something is a dimension of the research space.

Axial Coding – this is about trying to assemble that data after open coding. This can be done by using a diagram or some logic that connects things or looking for causes or looking for contexts and consequences.

Selective Coding – here the researchers invents a plausible storyline that integrates the categories in the axial coding model.

Matrix – a final step (though often omitted) is to produce a conditional matrix that is supposed to make clear the social, historical, technological or economic conditions that prevail in a situation.

Theory – one hopes that as a result of all this processing a theory will emerge which of course may go on to be tested by a formal experiment.

7.14 Rationale: Ethnography

This form of research is used when to immerse ourselves in the day to day life of an organisation or group. In this context ethnography is a description and interpretation of a cultural or social group.

1. Ethnography is commonly used when we want a reflective **description** expressed in an **interpretive** manner.
2. One can use this to look at individuals but more typically organisations.
3. Typically indicated when the research question starts with 'why'.
4. This is typically a qualitative study.
5. You cannot control the events being looked at but the events need not be contemporary.
6. You may alter the events being looked at because you are normally a participant observer.
7. Be clear as to how the data will be collected – by participant observation.
8. Ethnography is about immersion in a culture: behaviours, language, structures and functions.
9. In such studies one often encounters gatekeepers, key informants and communication relies on a sense of reciprocity by investigator and his subjects.

7.15 Rationale: Requirements Gathering

Requirements are simply a statement of a systems service (what it must do) or constraints (what it does not necessarily do). In practice saying what a system must do is often extended to how it will do it. This method is a form of action research but it differs in that the only contact one has with the people involved is at the requirements stage and possibly at the implementation stage though this may vary depending on the systems life cycle employed. You should use this method when you are setting out to build an application of some kind such as a computer application. There are 4 stages of requirements.

Functional Requirements - These are requirements that say what a system does or is expected to do. Typically this would involve or include most of the following: process descriptions, details of all inputs/outputs and details of all the data that must be held in the system.

Performance Requirements - This is usually understood to mean requirements that describe aspects of the system that are concerned with how well it provides the main functional requirements. For example: performance criteria such as response times or how long it takes to print a report, data throughput and storage needs and security considerations.

Technical Requirements - This aspect of requirement looks at the tools and method used to build the system. For example, it may happen that you have to use a certain database package or for other reasons you need to select a particular scripting language and so on. More often than not this aspect amounts to looking at technical constraints that must be applied in building the system.

Usability Requirements - Requirements that ensure that there is a good match between the system and its users. In most cases usability is expressed in terms of measurable objectives.

7.15.1 The Requirements Document

The system and software requirements are usually documented in a formal manner so that ones understanding may be communicated to customers and system builders. The requirement document describes the following:

Services and Function – that the final system must deliver.

Operational Constraints - under which the system must operate.

Development Constraints - on the process used to develop the system.

Properties of the system - in the sense that it may have unplanned additional functionality.

Links - definition of other systems with which the system must integrate.

Domain - Information about the application - for example how to carry out certain tasks.

Definitions – acronyms, abbreviations etc.

7.15.2 Stakeholders

These are people who will be affected by the system and therefore should have a direct or indirect influence on the system requirements.

7.15.3 A Process Model

As a process model we might define the requirement process as follows.

7.15.4 Requirement General Questions

There are perhaps four general questions we might ask when attempting to gather requirements

Problem - What are the problems with the current processes?

Improvements - What are the improvement goals?

Reference. Kotonya, G. and Sommerville, I, (1997), Requirement Engineering, Wiley, ISBN 0-471-97208-8. This book is useful because it also contains excellent reading and reference lists.

7.16 Research Design

Finally, you must set out your research design. That is, explain how you will get your data – and this must be done in great detail. In summary, then, your research design is the blueprint of your research project which enables you to deal, systematically, with:

What questions to study?

What data is relevant?

What data to collect – you will need to work very hard here so that you can rely on your data.

Are there any practical limitations to what you can do

How to analyse the results – don't shirk this.

How to decide in which contexts your findings are applicable or can be exploited.

The main purpose of your research design is to help you avoid a situation in which the evidence you eventually collect does not address your initial question.

7.17 Research Process Development

It is quite common is many kinds of research but notably in Case Study and Action Research for the researcher's perceptions to change as data emerges. Often this will imply that the research design has to be changed or amended if it is to remain meaningful. These changes may be small such as a slight modification to the Research Question or aim but occasionally it may be necessary to make significant changes. For this reason researchers must always be careful in their design to allow a little flexibility if they can to accommodate possible unforeseen circumstances.

8. WORKBOOK 8 - BIBLIOGRAPHIC REFERENCING HARVARD APA

This workbook is a short summary of the APA style guidelines as contained in The Publication Manual of the American Psychological Association, 5e, 2001 (Subject Reference Collection: 808.02 AME).

The APA style is based on the Harvard referencing system whereby the date of publication follows the author name(s), and in-text references refer to items in the reference list using the author surname and date of publication, in brackets.

Referencing is important in all academic work as it indicates to the reader the sources of your quotations and borrowed ideas. Failure to indicate your sources is tantamount to plagiarism (literary theft). The purpose of the referencing system is to describe your sources in an accurate and consistent manner and to indicate within the text of your paper where particular sources were used.

Please note that there are two sections to this document:

How to **reference** correctly a source in the **bibliographic** section of your work

How to **cite** correctly a source in the **written** part of your work

Don't Get Caught Out! If you do not reference correctly you may lose marks or your work may be returned unmarked to you for correction. Therefore:

Keep a careful note of all sources used as you prepare your assignments.

Record all the details you need about a library book (including page numbers for any quotations) **before** you return it - someone else may have the book if you try to go back and check later.

Make sure you write down the source details you need on any photocopies or downloads you make.

Remember to print or save details of any website you want to refer to and record the date when you accessed the information.

8.1 Reference list (Bibliography) at end of Project/Dissertation

The reference list should be arranged alphabetically by author surname. The APA format requires book and journal titles etc. to be italicised, although we are not strict about that.

As a rule in projects and dissertations it is normal to produce two lists. The first is a reference list and that **MUST** only include sources you have cited. The second is a bibliographic list which includes all other sources you might have found but did not cite – this list is to allow the reader to explore the topic further if they wish.

8.2 Books

The details needed for a book can normally be found on the front and back of the title page. Make sure you locate the name of the publisher rather than the printer or typesetter. You need the name of the publisher in your reference list. Ignore any reprint dates; you need the date when the first, second, third edition etc. of the book was published according to which edition of the book you are using.

8.3 Journal articles

The details needed for a journal article can usually be found on the contents list, front cover or article itself.

8.4 Printed publications: Examples of References

The following are sample if how to correctly reference a source.

Book – pattern: Author, Initials. (year). Title of book. Place of publication: Publisher.

American Psychological Association. (1994). Publication manual of the American Psychological Association 4e. Washington, D.C.: Author.

Encyclopedia of psychology. (1976). London: Routledge.

Gardner, H. (1973). The arts and human development. New York: Wiley.

Moore, M. H., Estrich, S., McGillis, D., & Spelman, W. (1984). *Dangerous offenders: the elusive target of justice*. Cambridge: Harvard University Press.

Strunk, W., & White, E. B. (1979). *The elements of style* (3rd ed.). New York: Macmillan.

Note: Only list up to 6 authors. The 7th and subsequent authors are abbreviated to et al.

Edited book

Maher, B. A. (Ed.). (1964-1972). *Progress in experimental personality research* (6 vols.). New York: Academic Press

Article in edited book (Chapter) - The basic pattern for a reference to a chapter in an edited book (where the chapters have been written by several different people) is:

Author of chapter, Initials. (year). Title of chapter. In Initials. Name of Editor/s (Ed.) *Title of book* (pp.start and end page numbers of chapter). Place of publication: Publisher.

Vygotsky, L. S. (1991). Genesis of the higher mental functions. In P. Light, S. Sheldon, & M. Woodhead (Eds.), *Learning to think* (pp. 32-41). London: Routledge.

Encyclopedia entry - If the entry has no author, begin the reference with the entry title followed by the date of publication.

Lijphart, A. (1995). Electoral systems. In *The encyclopaedia of democracy* (Vol. 2, pp. 412-422). London: Routledge.

Government publication

Great Britain. Command Papers. (1991). *Health of the nation* (Cm 1523). London: HMSO.
Great Britain. Home Office. (1994). *Prisons policy for England and Wales*. London: HMSO.

Report

Birney, A. J., & Hall, M. M. (1981). *Early identification of children with written language difficulties* (Report No. 81-502). Washington DC: National Educational Association.

Conference paper in published proceedings

Borgman, C. L., Bower, J., & Krieger, D. (1989). From hands-on science to hands-on information retrieval. In J. Katzer, & G. B. Newby (Eds.), *Proceedings of the 52nd ASIS annual meeting: Vol. 26. Managing information and technology* (pp. 96-100). Medford, NJ: Learned Information.

Journal article - The basic pattern for a reference to a journal article is:

Author, Initials. (year) Title of article. *Title of journal*, Volume number - if there is one (Issue number), start and end page numbers of article.

Noguchi, T., Kitawaki, J., Tamura, T., Kim, T., Kanno, H., Yamamoto, T., et al. H. (1993). Relationship between aromatase activity and steroid receptor levels in ovarian tumors from postmenopausal women. *Journal of Steroid Biochemistry and Molecular Biology*, 44(4-6), 657-660.

Popper, S. E., & McCloskey, K. (1993). Individual differences and subgroups within populations: the shopping bag approach. *Aviation Space and Environmental Medicine*, 64(1), 74-77.

Weekly magazine article

Barrett, L. (2001, August 23). Daewoo's drive to survive in the UK. *Marketing Week*, 22-23.

Newspaper article

Caffeine linked to mental illness. (1991, July 13). *New York Times*, pp. B13, B15.
Young, H. (1996, July 25). Battle of snakes and ladders. *The Guardian*, p. 15.

Two or more works by the same author(s) with the same publication date - Where an author (or particular group of authors) has more than one work in a particular year, list them in title order and follow the date with a lower case letter a, b, c, ... For example:

Harding, S. (1986a). The instability of the analytical categories of feminist theory. *Signs*, 11(4), 645-64.
Harding, S. (1986b). *The science question in feminism*. Ithaca: Cornell University Press.

Anonymous works - If a work is signed "Anonymous", your reference must begin with the word Anonymous, followed by date etc. as normal. If no author is shown, put the title in the normal author position.

Note on source page numbers - Use pp. for page range only for encyclopedia entries, multi-page newspaper articles and chapters or articles in edited books. For articles in journals or magazines use the numbers alone.

Interviews and email messages - Because interviews and email messages are not considered recoverable data, you do not give details in your reference list. You should, however, cite an interview or email message within the body of your text as a personal communication: ...and this point was conceded (J. Bloggs, personal communication, August 22, 2001)

Legal References - Because the situation regarding legal references is complex and only US law is covered in the APA Manual, legal references will be covered in a separate guide.

Audiovisual sources: examples of references - Such sources are often complex but please note.

Films - The basic pattern for a reference to a film is:

Name of primary contributor - the director or producer, or both, Initials. (Role of primary contributor). (year). *Title of film* [Motion picture]. Country of origin - where the film was primarily made and released: Name of studio.

Reed, C. (Director). (1949). *The Third Man* [Motion picture]. United Kingdom: British Lion/London Films.

Spielberg, S. (Director). (1993). *Jurassic Park* [Motion picture]. United States: Universal Pictures/Amblin Entertainment.

If the film doesn't appear on the Library Catalogue, the Internet Movie Database <http://uk.imdb.com/> is a good place to check all the details needed for a film reference (follow the Company credits link to find details about the film studio/s involved). Alternatively, check Halliwell's Film and Video Guide.

Review of a film - If the review is untitled, put everything in square brackets in the normal title position and keep the square brackets.

Kinder, M. (2002). Moulin Rouge [Review of the motion picture *Moulin Rouge*]. *Film Quarterly*, 55(3), 52-59.

Malausa, V. (2001). Beauté du mensonge [Review of the motion picture *The Tailor of Panama*]. *Cahiers du Cinéma*, 558, 82-83.

Television programmes

Collinson-Jones, C. (Producer), & Dobson, E. (Director). (2003, July 14). Casualties of peace [Television broadcast]. London: Channel 4.

Single episode from a television series

This example shows the most complete information possible for a television episode. If details of the writer are unavailable, begin your reference with the name of the director.

Fraser, R. (Writer), & Geoghegan, S. (Director). (2003). Eyes wide open [Television series episode]. In P. Goodman (Producer), *Holby City*. London: BBC1.

Radio programmes

Portenier, G. (Producer). (2003, July 17). *Crossing continents*. London: BBC Radio 4.

Electronic sources: examples of references - The details shown below have been compiled according to the guidelines available on the APA Website (<http://www.apastyle.org>) in August/September 2001 (re-checked July 2003). Check this Website and the 5th edition of *The Publication Manual of the American Psychological Association* which is available in the Frewen Library for further guidance.

The basic pattern for a reference to an electronic source is:

Author, Initials. (year). *Title*. Retrieved month, day, year, from Internet address.
Banks, I. (n.d.). *The NHS Direct healthcare guide*. Retrieved August 29, 2001, from <http://www.healthcareguide.nhsdirect.nhs.uk/>

If no date is shown on the document, use n.d.

If the author is not given, begin your reference with the title of the document.

If a document is part of a large site such as that for a university or government department, give the name of the parent organisation and the relevant department before the Web address:

Alexander, J., & Tate, M. A. (2001). *Evaluating web resources*. Retrieved August 21, 2001, from Widener University, Wolfgram Memorial Library Web site: <http://www2.widener.edu/Wolfgram-Memorial-Library/webevaluation/webeval.htm>

Deciding your future. (2000). Retrieved September 5, 2001, from University of Portsmouth, Careers Service Web site: <http://www.port.ac.uk/departments/careers/plancareer/deciding-your-future.htm>

Electronic journal articles which are duplicates of the printed version - Use the same reference format as for a printed journal article but add "Electronic version" in square brackets after the article title:

Lussier, R. N., & Pfeifer, S. (2001). A crossnational prediction model for business success [Electronic version]. *Journal of Common Market Studies*, 39(3), 228-239.

If you are referencing an online article where the format differs from the printed version or which includes additional data or commentaries, you should add the date you retrieved the document and the Web address (URL).

Articles in Internet-only journals

Korda, L. (2001, July). The making of a translator. *Translation Journal*, 5(3). Retrieved August 21, 2001 from <http://accurapid.com/journal/17prof.htm>

Use the complete publication date shown on the article.

Note that page numbers are not given.

Whenever possible, the URL you give should link directly to the article itself.

Break a URL that goes onto another line after a slash or before a full-stop. Do not insert a hyphen at the break.

Articles retrieved from a database - Use the format appropriate to the type of work retrieved and add a retrieval date, plus the name of the database:

McVeigh, T. (2000, July 9). How your gestures can do the talking. *The Observer*, p.7. Retrieved September 10, 2001, from The Guardian and The Observer on CD-ROM database.

8.5 Citing references in the text

There are basically two forms. The first is when the author's name is naturally part of the sentence and the second when it is just a reference. References are made from the text of the paper to the full details of the work in the reference list in the following manner:

It is a contention of the paper, and this contention is supported by Williams (1995, p.45) who compared personality disorders ...

When an author, or group of authors, has more than one publication in the same year a lower case letter is added to the date. For example:

In two recent works Harding (1986a, p.80; 1986b, p.138) has suggested that ...

With two authors both names should be listed in each citation e.g. Duncan & Goddard, (2003, p.99)

With three to five authors name all authors the first time, then use et al. (and others). For example: the first time it would be Moore, Estrich, McGillis & Spelman (1984, p.33) and subsequent references to the same publication would use Moore et al.

For six or more authors, use et al. after the first author in all occurrences.

Note that when the in-text reference occurs naturally within the sentence "and" should be used before the final author.

When a source has no author, cite the first two or three words of the title followed by the year. For example:

... in the recent book (*Encyclopaedia of psychology*, 1991, p.62) ...

... in this article ("Individual differences," 1993, p.12) ...

Web pages where no author is given

However, if the author is designated as "Anonymous", cite the word Anonymous in your text e.g. (Anonymous, 1993, p.116).

When using quotations in your text

Try to observe the following methods.

Gardner (1973, p41) stated that, "The relative importance of the systems may nevertheless remain in approximately the same proportion"

Smith (1991, p84) found that "...there is no evidence that chimpanzees can produce a drawing and discern the object represented in it..."

Occasionally, very occasionally you may need to cite a work that you discovered in another work because you cannot find the source then observe the following examples:

Smith (1970, p.27) cites Brown (1967) as finding ...

Brown (1967), cited by Smith (1970, p.27), found ...

It was found (Brown, 1967, cited by Smith, 1970, p.27) that ...

If you need to use this form your tutors must approve it and you must show that you have made every effort to track down the primary source.

9. WORKBOOK 9 – WRITING UP A RESEARCH PROJECT

This document is in several sections covering everything from project supervision to grading.

9.1 Your and Your Supervisor

The student supervisor relationship is very important if a high quality project is to be the outcome. As a rule the supervisor will be interested in the topic area and will want to be active in its development although you as a student must do the work. However, your supervisor will not be expert in everything but will usually have some knowledge of simple statistics and the four main research methods: experiments, action research, surveys, case studies and application development.

9.1.1 Student Expectations

The normal expectation is that students have of their supervisor are as follows:

- Only be available for consultation for a limited time.
- Only supervise what the student does and not do the work for them.
- Advise on research design, scheduling and literature surveys.
- Advise on theoretical, conceptual and methodological issues.
- Advise on development of research skills.
- Advise on data collection, processing and analysis.
- Advise on ethical issues if they are relevant.
- Read, evaluate and be constructively critical of student work if given sufficient time.
- Have a good knowledge of the general area you are working in.
- Be in contact with the student regularly.
- Arrange if necessary supervision chat sessions.

For project students on distance learning programmes it will be possible to have meetings in the WebCT chat room, using IM or Skype where a full and detailed interaction can take place. These must be agreed with your supervisor and must be planned not to clash with other classes. However, some tutor may allow student to contact them any time they are seen to be online.

9.1.2 Departmental Expectations

Supervisors take a formal role and certain attitudes and actions are expected. In general they will:

- Visit the discussion board and email regularly within WebCT (at least 3 times per week).
- Set a mail forwarding address to their personal accounts in WebCT email settings.
- Devote at least 6 hours to the supervision process spread over the project duration.
- Conduct one-to-one chats as required with project students.
- Conduct student/supervisor communication within WebCT or their personal email account.
- Respond to a student query within a certain time frame (normally no longer than 3 days).
- Be familiar with all the project guidance notes and workbooks.
- Be familiar with the project chapter profiles.
- Make sure students know if they are to be away for an extended period.
- Be aware that students may make contact though any one of their three WebCT accounts.

The essence of online supervision adequacy is based on the quality of communication between supervisor and student with the intent that we want the learning experiences to be exiting, stimulating and self-rewarding. In practice this means that communication must be frequent, lucid, critical and yet encouraging.

Supervisors should be aware that if they set email forwarding in WebCT they will effectively get an automatic alert when there is mail for them. If the student has also set mail forwarding then supervisors will be able to reply immediately otherwise they will have to go into WebCT. However, there is no alerting mechanism if a student posts a question into discussion so supervisors must visit the site from time to time so as not to miss any messages.

9.1.3 Supervisor Work Reviews

Supervisors will read your written work. However, when they do this certain rules apply:

Finished work – you should supply your supervisor with written work as it is produced chapter by chapter but it must be finished work. In this context finished work means that the format and content are the very best you can produce and in accordance to the guidelines found in this workbook. The tutor's role is not to act as some kind of filter for rough work or polishing multiple drafts which you want to improve in effect making them do the work for you. If a tutor suspects that the section you have sent in is not in its final form they will return it to you without comment.

Action on Feedback – if you are given feedback on any part of your work then you are expected to study it with care and commitment. However, it is up to you how to respond or even ignore what you are told but in all cases the consequences that follow are entirely your own responsibility.

Responding to Feedback – in all cases you are expected to respond to feedback. This may take several forms: writing to your supervisor saying that you don't agree with him or perhaps offering further explanation or as in most cases making changes to the content or structure of your project document. When you make document changes in response to feedback they are to be shown **shaded** so your supervisor can easily see exactly what you have added or amended.

Questions to Tutor - your tutor will not answer any questions regarding whether your work is right, wrong, is it a pass, what mark will I get or is it good enough. The only thing you can expect in this area is that you tutor may advise you that the work is not ready for submission to the university. If this happens it will be entirely your own decision whether to submit or not.

Response from Tutor - in most cases you supervisor will only suggest that you do something or ask a question designed to point you in a new direction. Normally, the tutor will not supply you with any project content since that must be provided entirely by you. The reason is that the work is yours not the supervisors.

Preparation - Your supervisor will expect you to be familiar with all the notes and workbooks contents. You should therefore be careful that you don't waste supervision time asking questions to which you already have the answers.

9.1.4 Chat Session

Chat sessions for project students will usually be one-to-one and are typically used when there are particularly awkward difficulties – chat will NOT be the norm during projects and your tutor will have no expectation that chat will be used.

9.2 Overview of Project Structure

Here are some general guidance notes – they are NOT suggested chapters but general content guidance on the project as a whole and have a sharp process focus.

9.2.1 Introduction summary

This is about the problem theme and its setting, client context, topic area, personal theory, Research Question or application functional description and intended project outcome, general research orientation followed by a well-define aim and sound set of objectives. The introduction is to be precise, concise taking a discussion form that is explanatory and focused on giving readers a clear, coherent and comprehensive view of what the project is about.

9.2.2 Preparation for Research

This is your study of the topic area and research methods that you will need to know about. You will have to justify and explain the methods you intend to use; it is also your study of other people's work in the area that you wish to investigate - and a description of how you learned from their research.

Literature Review - What has been done before in this area - related to a particular problem theme and Research Question. This is all about preparing ones mind with all the topic area and research knowledge you will need.

Research Review - research into how the project investigation could be done and supported. At this stage student will already have an outline plan based on their approve specification but now the whole design must be thoroughly reviewed before actual work begins.

Knowledge of Alternatives – build a simple decision base which allows one to consider which methods could be used and how could they be used for this project.

Choices Made - which methods are to be used and rationally consider why they are good enough for the purpose.

9.2.3 Core Research

Here you execute the refined research design translated into a practical plan to obtain the collection of primary data and process it using acceptable methods into the intended project outcome.

9.2.4 Evaluation and Conclusions

This is the stage that looks at how one finishes off a project by a process of evaluation and the drawing of conclusions. In particular, it is needful to look at how one evaluates what was done and how it was done – that one needs to consider the project product (or outcome) and the project practice. For our purposes evaluating will be taken to mean reflecting on product and practice.

Many students confuse evaluation and conclusions but for a full consideration of the research work one must look at all project specific results and outcomes as well as practices and evaluate them and then perform the more difficult step of drawing generalised conclusion about both product and practice.

Evaluation of Project Product – the project outcome or product is normally evaluated against objectives, other existing products, using defined criteria or some form of expert evaluation. Additionally, one needs to be aware of any constraints that might have an impact on the applicability of the outcome

Evaluation of Project Practice - evaluation of project practice is more difficult than evaluation of project product and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way'. Additionally, one needs to be aware of any constraints involved, including time management that might have impacted on the use of best possible practices.

Conclusions - need to be considered thoughtfully as this is the point where one looks for implications and meaning that arise out of an attempt to generalise the findings.

9.3 Writing up your Project

The following sections describe elements that occur in almost all projects and which are generally important in constructing scholarly work. Do not be tempted to ignore these instructions – anyone who departs from the spirit of them may have their work returned for correction prior to formal marking.

9.3.1 Main Project Body Page Layout

The following example shows how each page of a project report should look, note that each chapter should start on a new page and that it is NOT necessary to actually say Chapter 1, Chapter 2 and so on as it is the heading that is important. Do not use numbering to greater than to three levels but you may use indented (but not bulleted ones) entries within a section at any level.

1. QUALITY CONTROL IN PROGRAM DEVELOPMENT

In this chapter the nature of quality will be discussed and its relation to physical measurable properties that might characterise quality.

1.1 INTRODUCTION

This project discusses a possible strategy for devising a program development methodology that goes some way to guaranteeing the qualities of the delivered system. In particular it will concentrate on just two aspects - that of developing generic designs and code and how such designs could be assessed for quality and function. The strategy is based on the simple premise as endorsed by leading authors in the field such as Blenkinsop, Wilson and Bowers that categories of problem can be identified and formalised. It is the contention of this report that such a process would more or less automatically:

Reduce - the complexity of the design process itself.

Ensure - the quality of the final product by:

Giving managers more control over the product development cycle.

Giving users more idea of the kind of system they are likely to get and much more say in what the shape of the product will finally be.

Releasing programmers from the drudgery of having to design the same piece of code over and over again, thus enabling them to concentrate their efforts on new

Formatting Note – you are encouraged to use these two forms of indenting: one with a heading in bold and one without as a means of structuring and indented section. The use of bulleted indents is not recommended anywhere in a project document.

1.2. Multiplicity of Design Factors

Every programmer has had the difficult experience of having to read and understand programs written by someone other than himself or herself. The sort of problem encountered may be aptly expressed in the following lines.

Everything has been thought of before, but the problem is to think of it again. (Goethe)

Many other authors, notably Frewin (1989) have discussed the notion of 'quality model ratios' and in essence this idea means that software systems have an implied model which can be accessed for

1.2.1 Multi-Tier Systems

In modern client sever systems

1.2.2 Interface Facades

In this case we look closely at the Internetetc

9.3.2 Plagiarism Checking

A software tool will check all your sources automatically and if plagiarism is suggested it will be dealt with very seriously since the reputation of the whole course and of the University is at stake. You must remember, that copying, paraphrasing, summarising and similar techniques where the material is extracted from a source must be properly acknowledged.

A simple rule is that if you use more than 6 consecutive words from a source it must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

9.3.3 Writing Abstracts and Identifying Keywords

The function of an abstract is to summarise your project, its context and its conclusions in order to give the reader an overview of the main project theme so that they can make an informed decision on whether they want to read the entire report. A good basic structure might be defined as follows but it will usually be limited to around 300 words.

What was the project about?

What did you actually do?

What were the conclusions?

It is normal to add keywords or phrases after the abstract to act as specific pointers to content. There are no particular rules about how to construct these words or indeed how many there should be but typically there are 5 or 6 and to be useful they must be chosen with care in the sense that they might in themselves be regarded as a sort of abstract of ones work.

9.3.4 Standard Appendices

Project reports MUST include the following appendices:

Your Project specification – it may be brought up to date from that submitted at the start

Your project plan expressed in an appropriate format

A glossary if this is appropriate

A full reference list of work that you cited

A bibliography (may be combined with your citation list)

Each Appendix should be introduced by a title where the number (12 in this case) should follow on from the numbering within the body of the report: **12. Appendix A – Project Specification.**

9.3.5 Typical Project Organisation

Below is a suggested organisation for your complete project.

Briefing Pages

Heading pages (examples follow later in the section)

Plagiarism declaration

Abstract for Report including keywords

Acknowledgements

Dedications

Content list (automatically generated) for all headings, tables and figures/graphs etc

Introduction:

Brief topic area outline and background to problem
Presenting Problem definition
Real World Target relevant to the problem
Speculation of problem causes and possible solution routes
Personal Theory on the best solution route
Research Question/Application Description
Discussion of expected project outcome
Scope of work
Aim & Objectives

Literature Research (see Workbook 5 for recommendation for various project styles)
Detailed consideration of elements that help you focus on your topic area

Research Design

Research Method and its rationale in dealing with the research question/application
Process to collect Primary Data
Processing of the Primary Data to get an outcome

Application Testing (Engineering project only)

Design of Tests
Test Results and conclusions to be drawn from testing.
Implementation plans

Results Discussion and Presentation (study projects only)

Discussion and presentation of results
Generation of intended project outcome

Evaluation (these are specific to what you did)

Detailed evaluation of what was actually done – your practice
Detailed evaluation of your project product/outcome including objectives not met
Met/Not met objectives

Conclusions (here one tries to generalise what was done)

Generalisations based on a consideration of both product and practice
It is also possible to examine the following minor conclusion elements

- Usefulness of literature sources
- Future work/development
- Relevant aspect of the course used during the project period
- Changes one would make if project were repeated
- What you have learned
- Value-added features

References and bibliography (see workbook 5)**Content of Appendices**

The following items must be in a set of Appendices. These may be bound separately if the composite document becomes too large (more than 100 pages).

- Code listings
- Project Specification and project schedule
- Inclusions (copies of relevant documents such as policies, invoice layouts, diagrams etc)
- Questionnaires.
- Summary interview transcripts
- Details test plans
- Requirement catalogues
- Glossary
- Other

9.3.6 Project Types Sample Outline Contents

Broadly speaking there are two kinds of project: engineering where you build an application of some kind and study based where one would investigate in depth some idea. Here are some sample contents lists that show chapter or section headings for the different project styles. However, if it is obvious that these samples have just been copied into your project with minor changes then your work will be rejected. See Workbook 9 section 9.3.5 for further general details.

Sample Study Style Report Contents	Sample Engineering Report Contents
Title: Internet Marketing – A Users View	Title: BrokerBase – Insurance Sellers Information System
Chapter 1. Introduction to Internet Marketing	Chapter 1. Introduction to System
Introduction and contextualisation IT marketing problem theme Problem Theme and target Speculation and Personal Theory Discussion and Exploration of Research Question Project aim and objectives	Introduction and Situation Overview Situation based Presenting Problem Application background and context Application overview Project aim and objectives
Chapter 2. Literature Review	Chapter 2. Literature Review and Application Scenario
Introduction to Internet Marketing Marketing Planning eCommerce Technologies and Tools Costs and Benefit Estimation Consumer Orientation and Market led operations IT supported Marketing and selling techniques Product, Price, Place, Promotion and Customer expectation IT supported Experiential marketing Security protocols and languages Auditing and secure payment systems	Outline of Insurance Brokerage practice Background Review of the Application Scenario Outline of Application Build Process and Tools
Chapter 3. Research Design	Chapter 3. Requirements Specification
Research Method Selection and Rationale Primary data collection process Data specification Data locations and expectations Collection Protocol Processing of Primary Data Collection Outline Results Project Outcome	Outline of the requirements (requirement catalogue into appendix) Research Plan for requirement gathering: functional, performance, technical and usability Outline Requirements catalogue Analysis and Evaluation of requirements
Chapter 4. Evaluation (Project Specific)	Chapter 4. System or Application Design
Evaluation of Project Outcome Evaluation of Research Methods and Protocols used	Principles used for this design Overall system design Build Process Overview Database design Component design Interface design including website
Chapter 5. Conclusions (Project Generalisations)	Chapter 5. System Implementation and Testing
Generalisations on the research Outcome Reflections on what was learned etc	Testing strategy Testing plans (detailed plan placed in appendices) Test results (detailed report placed in appendices) Application Implementation plans
	Chapter 6. Evaluation
	Evaluation of the application Evaluation of practice (methods and tools used)
	Chapter 7. Conclusions
	Generalisations based on the Application Reflections on what was learned Future work Etc
Notes	
1. Whatever the project styles the appendix must include: the project specification, glossaries, references lists, bibliographies. The appendices may be attached to the main report or they may be placed in a separate document.	
2. Remember these are just samples and you may well have different numbers of chapters and different heading and sub-headings	
Table 6. Sample Project Content Outlines	

9.4 Report Writing

In your research you will often have to write reports and of course you will have your final report to write. Reports are a special form of writing and therefore you need to note that reports are:

- Written for defined purpose.
- Written and targeted at specific audience.
- Written systematically to present your findings.
- Focused on what you have done.
- Information structured and formatted to lead reader quickly to main themes and findings

9.4.1 Structural Elements

The following tables are intended to give you some guidance on how to construct report in a scholarly fashion and in a way that leads to clear and concise presentation. It is important to structure all your work in a way that enhances its usefulness and utility. The following is a list of all the major structural elements, though there is no need to use all of them in every document you produce. The best advice is to choose a structure and then those elements that best suit the work in hand.

Structure	Description	Location
Title	A focused and short description of the document that summarises the deliverable element	Front page and above the contents list
Contents List	A short index based on the major chapters and/or sections	Before the main document begins but after the title page
Glossary	Used to list and describe special terms or abbreviations	Towards the end of the main document
Index	A detailed listing of all important words or phrases specifying location in main text	After the glossary if it exists otherwise after the main document
Appendix	For inclusion of explanatory notes, special documents or copies of originals	After the glossary but before the index
Footnotes	Notes at the bottom of pages and linked to pieces of text.	Immediately before the page footers
Headers	Standard text	Every page
Footers	Standard text	Every page
Keywords	Words or phrases used to form a simple classification of your work	Near front of report
References	List of all reference material in an approved manner	Toward end of document

Table 7. Main Document Physical Structural Entities

Organisation	Description
Chapters	Major elements in the development of the subject matter of the document
Sections	Minor elements in development of each chapter
Headings	Major Information Content indicators
Indents	Used to emphasise small but important points in the text
Bullets	Used to further emphasise an indented text
Tables	Used to represent important information concisely
Paragraph numbers	Used when it is necessary to reference all parts of a text
Page numbers	Used for indexing purposes
Diagrams	Used to show idea or data pictorially
Captions/Legends	Added to diagrams where necessary
Columns	Use when the subject material lends itself to such a view

Table 8. Main Document Structural Devices

Presentation	Description	Examples
Font	Letter style and size	May be proportional or fixed point
Renditions	Printed form of font	Bold, underline, italic, reversed
Orientation	Page format	Portrait or landscape
Form	Delivery form	Paper, electronic
Table 9. Main Document Structural Properties		

9.4.2 Report Writing Stages

There are a number of stages to writing a report and they require you to be focused on what you are trying to show as the core of your report.

What are your trying to show – this really goes along with the underlying purpose of your research question – typically this will be about wanting: to inform, to explain, to evaluate, to prove, to advise, to recommend, to predict or to bring about changes.

Collect and sift material – it is important to jot down ideas relevant to your purpose. These jottings will help you form an action plan for gathering information from other documents, visits, interviews, observation, surveys etc.

Note - information sources as you find them

Organise and structure the material - group your work into chapters, sections and sub sections. Make sure the order is logical.

Draft and edit/redraft – to get a good report you may well have to re-write it several times and this may include complete re-ordering. It is important that you need to be concise and use a formal language but it must be clear and concise. Use simple, straightforward words and sentence construction and make sure your spelling and grammar are faultless. Use clear headings and sub headings with bulleted indentations.

Thematic – make sure your work has clear themes that are easy to follow.

Plain English - do not try to be over-clever or fall into jargon.

Read Saunders chapter 13 pages 414 to 443. Don't skimp on this or I might skimp when I mark inferior work!

9.5 Summary and Advice

Your final project must have a strategic dimension. This does not mean you can't build some software but if you do it will be in support of a strategic objective. So whatever you decide to do consider:

Why it is being done but note it will not be sufficient to just say why, you will have to show evidence for your conclusion.

Cost/benefit is a useful idea but in most cases it is very hard to show benefits. In any case you need to look at other possible ways of showing that something is worth doing.

Don't forget life cycle logistics - that is what are the costs per hour (for example) of running a system for say a 10-year life.

Also look for impact for what you do. For example something might be cost effective but may have a negative affect on some business element.

Think through your ideas; don't be narrow - question everything.

Traditionally strategies are developed around two themes: needs - what are the business needs (at a high level) and what are the business values (what does it regard as important)

9.6 Project Submission Regulations

Successful project reports may lodged in the University library, it is therefore important that reports follow a standard binding format as described below. Project reports that deviate from these regulations may be penalised and returned to you for correction and in extreme cases, failed.

Submission - two full bound A4 portrait orientation copies of your report must be submitted by the defined dates. The report may NOT be submitted electronically – the copies must be sent by courier to reach us by the defined dates. However, you must also submit soft copies on either floppy disc or CD/DVD.

Presentation and Submission Checklist – your project report submitted using the correct form shown in Workbook 10. The form must be bound into your project.

Report Length - the maximum permitted report length is 15,000 words, which usually translates into around 50 to 100 pages (excluding appendices). If your report is likely to be significantly longer than this, consult your supervisor as to what to include and what to exclude. You are warned that should you exceed the permitted maximum length the University may return your work unmarked.

Binding - the project and any separate appendices should be securely bound using tape or book binding - if that is not available then plastic ring binding may be used. No other form of binding is permitted. Binding covers should be a card of weight of 140 gsm and the normal colour is to be RED but any other colour may used in case of sourcing difficulties

Front Covers Format - the front cover appropriately spaced vertically should conform to the pattern shown below using 24-point Arial Narrow with centred text and bold as shown. Do not include the square brackets when you complete these formats as they are just placeholders

University of Portsmouth

Technology Extended Campus

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[HEMIS No.]

Supervisor: [Name of supervisor]

Project unit Code [Project unit code]
[Month and Year, e.g. September 2004]

Title Page - the first project contents page, appropriately space vertically must contain the following information in the order shown below using 12 point Arial Narrow/Time Roman type throughout. Do not include the square brackets when you complete these formats as they are just placeholders.

University of Portsmouth

Technology Extended Campus

Master's project undertaken in partial fulfilment of the requirements for the

MSc [Degree title]

[Title of project]

by

[Full name of student]

[HEMIS No.]

Supervisor: [*Name of supervisor*]

Project unit: [*Project unit code*]

[Month and Year, e.g. September 2001]

Abstract - [The abstract of the project should be between 150 and 300 words in length and constructed to say what the project was about, what you did and what were the conclusions]

Keyword List - [List of appropriate key words]

Acknowledgements Page - it is common practice to add a page listing those you wish to thank for their help and assistance. As a rule acknowledgements should **only** be given to people who helped you directly with your work but were not involved in it. For example, if a colleague supplied you with a statistical analysis they should be acknowledged. However, it is not usual, necessary or desirable to acknowledge your parents, your friends or your supervisor.

Submission Form and Plagiarism Declaration

You must add the following two pages which require a signature. In practice one adds the signature to the final bound copies.

Declaration of presentation Standards

Include at this point a completed copy of the project submission page shown in workbook 10. Be warned, that if you tick this page and the relevant element is not found to be present, the work will be returned to you unmarked for correction.

Plagiarism Declaration

I confirm that the enclosed written work (including application code) is entirely my own except where explicitly stated otherwise. I declare that wherever I used copying, paraphrasing, summarisations or other appropriate mechanism related to the use of another author's work it has been properly acknowledged in accordance with normal scholarly conventions. I understand that wherever 6 or more consecutive words are extracted from a source they must be acknowledged and 10 consecutive words that are unacknowledged will be regarded as proof of plagiarism.

Signed _____ Date _____

Contents list, Table List and Diagram List

Include as appropriate

9.7 General Grade Criteria

Workbook 14 gives general guidance as to how projects will be assessed. Workbook 14 also contains a table of the criteria used, although the emphasis given to various aspects may vary depending upon the nature of the work and should be explained to students in assessment specific criteria.

9.8 Project Examination Board Reflections

This is a discussion based on observations made on the marking forms and in the Examination Board regarding the quality of the submitted document as final Master's projects/dissertations. Most of these faults are due to shallow and sometimes very shallow thinking on the part of the project student and that is unacceptable at Master's level. The following points are to help both supervisors and students avoid known pitfalls and so produce a project document to a high standard.

9.8.1 Project Introduction – Study Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem definition – common deficiencies were no discussion or poor discussion of what problem was being addressed by the project. Without such a discussion it is almost impossible for a reader to get any grasp of what the project is about. In projects we want to see just ONE major problem theme not several so it often requires clear thinking to set it at the right level. (See workbook 6 section 6.2 and 6.5)

Target and Outcome – there is often considerable confusion over these two ideas. The target is about what might happen in the real world based on the project outcome but often students cannot distinguish what the project will generate and what might be done with that project outcome. As a simple example, students might say that the project outcome is "improved accuracy in data entry" when what they mean one supposes is that in their project they will design (say) a new training programme that will be used to get the real work target of improved accuracy.

Speculation and Personal Theory – students are encouraged to speculate about problem causes and solution routes to arrive at a personal theory about the problem theme and how it might best be resolved leading to a suggestion of an expected form project outcome. A reader expects to see some indication as to what form the project outcome will take and in addition some discussion of the form to at least show that it is likely to go some way to resolving the stated problem theme. Unfortunately, the form was often missing and even when the Research Design was consulted a typical reader could still not see what the project outcome was supposed to be. Here we want to see ONE major form outcome for each project. (See workbook 6 section 6.5).

Research Question - either missing, badly worded or multiple questions offered (sometimes all in one sentence). One common mistake was to ask a question in the form (or some equivalent) of "is it possible...." - the point is that in such questions the answer is almost always that it is possible so the research effort becomes pointless. (See workbook 6 section 6.7 and 6.9)

Process for Generating Primary Data - this is a key element in any project as it is essentially the main activity used to unlock the primary data. It is useful to discuss this process briefly in the introduction since that allows readers to link the problem theme and therefore see what data you are likely to be looking for.

9.8.2 Project Introduction – Engineering Projects

There have been many examples of very poor introductory chapters and in some cases it has led to failure. The main reasons are omission, or very inferior expressions of:

Problem Theme - there was either no discussion or poor discussion of what problem theme the application being built was supposed to resolve. When this happens it is almost impossible for a reader to get any grasp of what the project is really about. (See workbook 6 section 6.2 and 6.5)

Functional Description - many students could not provide a short functional description of the application they were going to build. The most common thing for students to do instead was to provide an overview of the application architecture. This is hopeless as architecturally almost all Engineering projects are the same in that they typically have a database and a webpage for example. This implies that students cannot or do not want to make a distinction between how an application is built and what its purpose is.

9.8.3 Aim and Objectives

In many cases these elements were missing altogether. In other cases one could barely link the aim to the Research Question or application description. However, of most concern was an apparent inability in many students to write a coherent and reasonable set of objectives. Not to be able to write an aim and more particularly objective is representative of a gross error and it should never occur in Master's level work.

Aim - usually composed in a reasonable way but there does seem to be an inclination in some students to cram everything into the aim as if they are some kind of superman. The recommendation is to have just ONE clear activity mentioned in the aim and that should be accompanied by a just one clear outcome for the aim. (See workbook 6 section 6.11, 6.11.1)

Number of Objectives - often there were far too many to be in any way practical for one student in the time available and often this was because they were all expressed at different levels of project resolution.

No Visible Outcome - there were many, many cases where the objectives had no visible outcome. Far too often we got phrases such as: "To understand...." or "To analyse...." without any object to the sentence so there was no outcome that was visible. Without a named outcome there is no way that the objectives can be seen to have been completed. (See workbook 6 section 6.11)

Not Project Bounded - there were many students who cited operational objectives as outcomes. For example it was common to see lines such as such things as "To improve the workflow in the invoicing section". Here is a case where such an outcome cannot be written into a document or be in practical terms viewed and so cannot be used in a project. Typically, unbounded objectives refer to something that might happen based on the project outcome after the actual project has been completed (See workbook 6 section 6.11)

Objectives as Requirements - very commonly but still rather worryingly, many students, on Engineering projects, seem to think that objectives are the same as application requirements. (See workbook 6 section 6.11)

Objectives as Benefits - less commonly but still rather worryingly, many students, on Engineering and study projects, seem to think that objectives are the same as benefits. For example, in a study project on CRM systems what one often finds in place of project objectives is a list of benefits of implementing CRM. Similarly, for Engineering projects we see objectives written as a set of benefits of using the application being built later on in the real world. (See workbook 6 section 6.11)

9.8.4 Literature Review

In research the literature review is regarded as being essentially preparation of the mind. It follows, that to be serious about this step one has to be evaluatory and reflective as you read and write. Ideally one needs a strong theme which is used to weave an expository and exploratory discourse that unites and builds one's understanding and ideas with what has been written by other authors on one's core topic area.

For projects a full literature review is only needed in the case of a study project. For Engineering all that is required is a thorough overview of the application area. So for example, if an application were about Insurance brokerage then all that is required is a description of what brokerage is but only to the level necessary to understand the requirements. With this aim in mind: (See workbook 5 but section 5.2 and 5.6 should be studied with care)

Structure - many reviews were poorly structured and one often felt that the students had just written down the material as it occurred to them without any thought as to a wider readership.

Theme - often there was no detectable theme connecting the various sections of the review narrative and a reader would therefore be forced to guess and see how all the various elements were connected.

Value Added - the most common flaw was to see a review that was entirely or almost entirely made up of quotations, paraphrases or summaries so that the 'hand' of the student was not detectable anywhere in the work. Such work is not evaluatory and gives no indication whatever that the student has learned anything of value or indeed anything at all. It is often the case that one feels the student has no notion of the literature being a driver that may mean they have to accept new knowledge, gain further experience, modify existing knowledge or even abandon what they thought was sacrosanct and sadly no belief that their own views and experiences are also important.

Citation Style - two things are evident here. Firstly, one finds that too often citations are limited to the Literature Review. Secondly, the actual style used is very poor and commonly we see the form (Burk, 1992 p45) placed at the end of a sentence or paragraph. This is not acceptable and can only mean the whole paragraph has been paraphrased. The ONLY correct use of this bracketed style is in a passing reference to a text. (See workbook 8)

Worthless Quotes/Paraphrases - it is unfortunately only too common to see an appeal to some text or other for information that tells you either common knowledge or makes an obvious observation and so the citation is worthless and is representative of weak scholarship and laziness where a student is just trying to add a citation because he knows that such things are desirable. For example, quoting an author who says that "Object Orientation is now routinely used in software construction" is representative of common knowledge or quoting an authors who "says change is inevitable in organisations" is something that one might regard as obvious.

9.8.5 Research Design

These were often far from satisfactory and often read like a joke delivered without the punch line. The students are taught that essentially there are two phases. The first phase is the process used to get primary data items that are formed into a collection. Once the collection phase is completed we move on to the second phase of processing where the collection of primary data is processed to get an answer in the form expected. Particular points are:

Research Phases - In many case students were unable to distinguish the processing needed to get a collection of primary data and processing of the collection of primary data to get an outcome. It is quite common to see these two phases ignored or become competed muddled leading to a poor research outcome because the student loses his/her focus and often appear to have no clear idea what they are doing. The phases are:

Phase 1 - a process or processes used to define and create a primary data collection. It typically has four steps: define the data based on the Basic Activity for Generating Data, locate the data sources, collect the data and present the data.

Phase 2 - a process or processes used to manipulate the collection of primary data to get the form of answer expected.

No Outcome - often it seemed as if the student had no idea what form of outcome to expect so when one looked at the processing there was no sense that the primary data was being transformed into the required form of outcome.

Primary Data - many students seem to have only a vague notion of what primary data is and will often, very often, confuse or think that primary data is the same as the method of collection. This confusion is often evident with some students thinking that only questionnaire data could possibly be primary data.

Primary Data Definition - Primary Data is new data in the sense that it will not exist as a collection until I (you) define, collect and record it. But it must be collected for a specific purpose in that the primary data collection is representative of some aspect of the area under investigation and can be processed to get a defined form of outcome that will resolve or partially resolve a stated problem theme. All projects must be based on the collection and processing of primary data.

For example, one student took the definition and then read through an accounting system manual for his company and extracted all the functions and claimed that was primary data because he was going to use it to define what an accounts package should have by way of functionality but seemed unable to see that the manual had effectively done that already. (See workbook 6 section 6.6)

Research Method Justification - often students could not distinguish between Research Method and Data Collection Protocols. Research Methods are frameworks such as Case Study, Experiment, Action Research and so on. Collection protocols are based on: interview, questionnaire, observation, role playing, seminars, focus groups and so on. The sorts of justifications used are of the form "I have chosen case study because Saunders (2005, p92) said case studies are good... This is hopeless and implies no real thought. Justification must be built from a sound understanding of a particular Research Question, its expected form of outcome and the Primary Data needs and at least an overview of which method is likely to be best in a given situation. (see Workbook 7)

Practicality - many plans were over-complicated with students trying to use multiple methods and then ending up with masses of data they had no idea what to do with. There is only limited time and so students should be encouraged to focus on just one Research Method although of course several protocols may be involved.

Data Collections - in many cases all an examiner was able to see were results but often one simply could not tell if any primary data collection was involved and the results just seemed to appear 'out of the air'. The marking guide is quite specific and projects must be clear about both processed data and raw primary data collections. Without this we cannot feel confident that students have done any actual research. Typically, the collection of primary data is placed in an appendix and might be in the form of a summary table of questionnaires results or summarised transcripts. Correspondingly, the processed primary data collection is expressed as charts, graphs, tables, reports and so on in the body of the project report.

Processing - this is one of the most disappointing elements. Processing is all about transforming your collection of primary data into the form of outcome expected. Far too often all we see is the processing of individual primary data items with no attempt or very weak attempts to really supply an answer to the Research Question in the form that was specified.

Location - there were quite a few projects where it was more or less impossible to see where the primary data came from and often this was accompanied by a very ordinary set of results that could have been written by almost anybody with a superficial knowledge of the subject area.

9.8.6 Research Results Processing

There were some very good examples but often this section was very routine and very disappointing.

Repeating - it was very common to see a chart for example, displayed and then underneath the student simply repeated the data that was in the chart in words. Such a practice is worthless. What any data related narrative is supposed to do is to tell the reader what the data means and what implication it might have - that is we expect to see some analysis and evaluation of the data in terms of the Research Question.

Focus - the focus of processing the primary data is to create a kind of transformation that generates from the collection of primary data the expected project outcome - unfortunately, this aspect was often absent. Typically in a survey for instance we have page after page of charts analysing individual data items but no attempt to sum it all up and reach a conclusion based around the Research Question.

9.8.7 Evaluation and Conclusions

These sections in a lot of student work are indistinguishable. The reason there are two sections with marks attached is because:

Evaluation - here one focuses specifically on the project outcome and research methods - that is we evaluate our product (outcome) and the methods used to generate it. Notice here this is NOT about generating the outcome that would have been done in the research processing section

Conclusions - here the attempt is made to say what it all means - that is trying to generalize the findings. So for example, suppose the outcome is about the use of Agent technology in eCommerce web sites then in conclusions one might try to say what a particular project outcome means for any eCommerce site or in fact any website. In a similar kind of way, if a particular application had been built we might try to say whether it might be applicable in other situations or whether some features of the design can be transferred to all applications of that type.

9.8.8 Ignorance of Project Marking Criteria

Many students show an almost complete disregard for the way a project is marked and so often automatically lose marks. Students must therefore carefully study the marking forms so that they know what components are regarded as essential to any project and therefore carry marks. (See workbook 11 or 12 as appropriate)

10. WORKBOOK 10 – FORM: PROJECT SUBMISSION

This form **must** be completed and included in your project submission. If you are unable to tick every box then your work is not ready for submission.

Project Word Count	Exclude appendices. If maximum is exceeded marks may be lost or the project rejected
	The report length is within the stated guidelines (15,000 words maximum excluding appendices)
	I have included all making elements indicated in workbook 11 Or 12 as appropriate and noted the marking guidance notes
	I have studied the guidance notes on common project faults found in section 9.6
	I have prepared two bound copies of all my project work including any separate appendices
	I understand that I may use one or both sides of the paper when printing the report.
	I have included a full contents list, table list and diagram list all numbered consistently
	I have used good quality A4 paper, normally in portrait orientation with a weight between of 80 and 100gsm.
	I have made sure that the pages are in the right order and none are missing
	I have used MS word .doc format
	I have formatted the front cover and title page as required and added the necessary plagiarism declaration.
	All my text is single line spaced at 6 lines per inch/25.4 mm.
	All my main text, including headings is in 12-point font (Arial Narrow is recommended)
	All my text in tables and diagrams is 10-point font (Arial Narrow is recommended)
	All main text is right and left justified
	No headings at whatever level are indented
	Headings are NOT followed by a blank line
	Headings are in the same font and size as the main text but are shown in bold type
	No numbered headings are orphaned (that is all heading must be followed by some text not immediately by another heading)
	I have used a single blank line to separate paragraphs
	All chapters and appendices are numbered sequentially (1, 2, 3,...)
	All subsections are numbered (2.1, 2.2,...) and none of my sections numbers exceed three levels (1.2.1, 1.2.3 ...)
	All my margins: (top, bottom, left and right) are 20mm
	All pages have footers in 10-pt Arial Narrow in form: Page 12 of 97 - J.Letto Student No. 567543 Submission Date: 12.10.07
	I have cited other people's work properly using the Harvard APA format
	I have included all citations in my list of references
	My abstract accurately summarises all of the report, not just parts of it
	All my chapters and appendices start on a new page
	I have included appendices, where appropriate, covering: project specification, Project Plan, Requirements document(s), design document, screen shots, source code, user documentation, test results, evaluation results, questionnaires, etc.
	My supervisor has read each chapter as the work progressed.
	My supervisor has read the whole report
	I understand that indented sentences can be used where appropriate but bullets are not recommended (see 9.3.1)
	I understand that page headers are not required
	I understand that each of my chapters should start with an introductory section that explains what the chapter is about
	I understand that each of my chapters should end with a summary and a helpful link to the next chapter
	I have fixed a copy in .doc format of the project document and any appendices on floppy/CD/DVD to my project submission
	All my primary data (including requirements data) is original to this study and collected by me for this specific project purpose
	My primary data collection is available in the project document or appendix (if necessary in edited or summarised form)
	Engineering Projects only - I have included an executable file of my application on an attached floppy/CD/DVD
	Engineering Projects only - Application Operating instruction are on the attached floppy/CD/DVD as well as in the appendix
	Engineering Projects only – In my application I have not used illegal copies of any software or included any software where there is an expiry date which may render the application inoperable in the future.
	Engineering Projects only - I understand that the copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If, and only if, this is not possible then I have included in my project a supervisor signed set of screen shots in the appendix confirming that he/she has viewed the application in action.
Signature of Student. _____ Date. _____	

11. WORKBOOK 11 – FORM: STUDY PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

STUDY STYLE		Postgraduate Project Marking Form						STUDY STYLE	
Name of Student							HEMIS No.		
Brief Project Title							Total Mark	%	
Recommendation	If the mark awarded is a fail circle your opinion						Re-Work	New Topic	
Name: Supervisor

Section E – Qualitative Assessment matrix based on University Grade Criteria									
1.	Length of the report	too long	a bit on the long side	a bit too short	needs expansion	about 12k words			
2.	Spelling and grammar	was full of mistakes	had many mistakes	had a few mistakes	a few minor mistakes	was flawless			
3.	Report structure	very poor	poor	satisfactory	good	excellent			
4.	Appendices to report	completely irrelevant	largely irrelevant to the report	mix of relevant and irrelevant material	mostly relevant	relevant and referenced in report			
5.	Student effort	clearly less than the required hours	less than the required hours	about the required number of hours	probably more than the required hours	clearly more than the required hours			
6.	Project idea	trivial	easy	modest	challenging	Difficult			

7.	Project aim	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
8.	Project objectives	unstated	vaguely discernible	stated but not clearly	clearly stated	precise and concise
9.	Literature review	not provided	superficial and not evaluative	Adequate with some evaluation	thoroughly evaluative	extensive, evaluative and relevant
10.	Ideas taken from elsewhere	not credited	not credited but minor	usually correctly cited	cited correctly	correctly cited and well used in the text
11.	Project content	entirely based on existing material	a rehash of existing material	nothing really new, but solid	partly original	totally original
12.	Primary data collection	no reliable data obtained	little reliable data obtained	some data obtained but only of a routine nature	useful data obtained but of limited scope	useful data obtained in a careful and planned manner
13.	Data processing	no evidence	vaguely discernable	stated but not clearly	clearly stated	precise and clear
14.	Main project outcome	Worthless	obvious	useful	original	exceptional
15.	Outcome evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
16.	Practice evaluation	not stated	trite	stated briefly and not based on the project	lacked reflective depth	insightful, original and reflective
17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Study Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes found in Workbook 14.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.2 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the topic area literature

Reference: Workbook 5 section 5.2 and 5.6 in particular, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers and generally be focused on the central project topic. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and its exploration including the Research Question

Reference: Workbook 3 section 3.3 and 3.5.1, Workbook 6 sections 6.2, 6.6 and 6.7 and Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Research Question with a defined form of answer (project outcome). It is very common to see an expression of a problem as "my problem is to find a solution to..." or expressed in such a way that it is in effect a solution and such expressions are indicative of students who do not know what the problem is but nevertheless know what the solution is. Similarly, students who list multiple problems, have no Research Question (or a very poor one) and do not discuss the form of outcome expected are embarking upon projects where there is no clear focus and these typically fragment when it comes to the core research and one most often cannot find any clear project outcome later in the work. It is also useful at this stage if there is some indication of the Basic Activity for Generating Data (BAGeD) so that one can feel sure that the student is aware of what primary data they need in order to generate the intended outcome.

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.2 (example), Workbook 6 section 6.1 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition, expected form of outcome and Research Question all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Selection and justification of Research Method

Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful choice of Research Method focused on resolving the stated problem theme. In practice this implies a consideration of primary data needs, location of primary data and the collection protocols that might be used. Markers should guard against rationales that amount to saying that some text book or other said method X or Y was good for certain kinds of scenario – that is copies of generalisations about Research Methods found in books do not amount to a rational for a specific research situation. Furthermore, markers need to feel confident that the student understands the distinction between a Research Method and the collection protocols used within them.

6. Primary data collection plan including data specification

Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

This is a crucial stage in a research based project and markers must be confident that the plan is practical. A marker must look for a clear core activity represented by a statement about of BAGeD and that core activity should be surrounded by whatever other processes are needed to ensure reliable collection of the primary data. The whole primary data collection plan has four steps which must be visible in the project document: data definition, data location, data collection and how the whole collection of primary data is to be presented. Markers should also take care that the formation of a collection of primary data is not confused with the processing of it to get the stated project outcome.

7. Primary data processing plan and presentation of the expected outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for clear evidence that the student has taken the collection of primary data they obtained earlier in the project and now process that whole collection to get to a clear presentation of the project outcome. It is therefore important that markers can see what processes were applied to the collection of primary data to get the outcome – without this process visibility there is no evidence as to how the project outcome was actually obtained. Markers should be wary of processing plans that say such things as “I will look at the data” or “I will analyze the data” or “I will use SPSS” as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same data collection they could apply the same processes and get the same or at least a very similar outcome.
Markers should also be aware that very often students will often process individual data items – such as might be found on a questionnaire, but never get to a point where the stated project outcome is derived from the collection of data.
8. Presentation and discussion of the collection of Primary Data
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for visible signs of the collected primary data. The primary data collection is most often presented in tabular form in the appendix and might be displayed as graphs, charts, tables or diagrams in the main project document.
9. Expression and description of main project outcome
Reference: Workbook 3 section 3.5.2 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
The intended project outcome must be clearly visible – for example if the intended outcome is a model then that must be clearly shown in some acceptable form and be based on the processing plan outline in section 7. Markers must therefore take great care that the presentation of primary data and the processing of individual data items in the collection are not offered as a substitute for the student generating the intended project outcome.
Section D - Marks for Project Evaluation and Conclusions
10. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project outcome so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution (project outcome) or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project outcome. The section is not intended for vague thoughts about the topic but a considered evaluation of the project outcome when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
11. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate here. This section is important as this is where one expects to find some information on what the student has learned about the way they work and the tools they used. It is unfortunately often the case that students have very little idea about what they did apart from stating vague activities such as “look at”, “analyze” or “use SPSS” so without anything concrete to evaluate they resort to the routine and say “the survey process went very well” or “my case studies generated useful data” or else they simply ignore this form of evaluation altogether. Evaluation of project practice is difficult and the most usual way is by asking searching questions related to process success and the notion of good practice and best practice based on performance criteria and simply asking ‘how did I do it’, ‘was it successful’ and ‘could I or should I on reflection have done it another way’. Additionally, one needs to be aware of any constraints involved, including time management and particular skills that might have impacted on the use of best possible practices.
12. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if a project outcome was based on case studies and the outcome was a review of IT outsourcing in Hong Kong then here we might expect to see the student consider the outcome he obtained which refers to Hong Kong and then consider and discuss whether that outcome has wide applicability, for example, to China, South East Asia or even the world as part of a Global economy or is it just specific to that local situation. Essentially, one is asking what do the outcome ‘mean’ when set in a wider setting. It follows that the focus of awarding marks here is for project generalisations.
It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such as future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

12. WORKBOOK 12 – FORM: ENGINEERING PROJECT MARKING

The form shown below is included for reference only so that you can see how your project will be marked.

ENGINEERING STYLE		Postgraduate Project Marking Form				ENGINEERING STYLE

17.	Conclusions	not stated	trite	stated briefly but mostly routinely observations	stated but not entirely derived from the project outcome	insightful, generalised and derived from the project outcome
18.	Overall assessment	very poor	a bit poor	satisfactory	pretty good	worthy of publication

Section F – Marker's Critical Comments

Section G – Note here elements you want brought to the attention of the External Examiners

Signed		Dated	
---------------	--	--------------	--

Engineering Format Marking Form Guidance notes

These notes must be read in conjunction with the grade criteria and associated notes.

Section A - Marks for Planning and Preparation

1. Project specification, including project plan

Reference: Workbook 3 section 3.3 for general notes and section 3.5.1 for an example specification

Marks should be awarded for a complete specification and a reasonable plan that spans at least 18 weeks study time. When examining the project plan markers should look for some degree of originality and an indication that it is related to the particular project and not just a copy, with changed dates, of one of the sample plans shown in Workbook 3.

2. Review of the application/product area and its client/business setting

Reference: Workbook 5 section 5.2 and 5.6, Workbook 8 and Workbook 9 section 9.6.4

Here one looks for a good structure based on a clear theme that supports and prepares a student for the core project activity. The material covered should be relevant and presented in a reflective and measured fashion with regard to its readers. In Engineering projects the expectation is that the review will focus on the application area and be in enough detail to at least understand and gather the requirements. It is permitted to include technical material if they have a special or unusual significance to the application area but in so doing students must be aware that the routine inclusion of what at this level might be regarded as common knowledge in computing/IT will not attract any marks. The review itself must be expository and evaluatory in nature and the 'hand' of the student must be seen as the literature is cited and used in the text. The key features are summed up in the acronym FRAMED whose explanation can be found in section 5.1.

Section B - Marks for Project Introduction

3. Presenting problem and Outline Proposal

Reference: Workbook 3 section 3.3 and 3.5.1 Workbook 6.2 and 6.5, Workbook 9 section 9.6.1

All projects are supposed to be based on one clear problem definition expressed at a suitable level of resolution. Markers must therefore feel sure that they know what that problem is and how the student has theorized about its nature, importance and its possible resolution and that discussion culminating in a lucid Application Outline expressed as a functional description. It is very common to see an expression of a problem as "my problem is to find a solution to..." and this is indicative of students who do not know what the problem is but nevertheless know what the solution is. Students who list multiple problems, have no functional description (or a very poor one) are indicative of projects where there is no clear focus and these typically fragment when it comes to requirements gathering and often end in a very trivial application. Markers should be aware that students may avoid giving a functional description and instead offer a generic architectural one and this must be penalised as the student clearly does not know what function the application supplies

4. Discussion of the project's scope, scale, aim and objectives

Reference: Workbook 3 section 3.5.1 (example), Workbook 6 section 6.11, 6.9 and Workbook 9 section 9.6.3.

Markers should look for an aim expressed ideally as a single action leading to an identifiable target related to the problem definition. The aim is to be supported by a sound and sequential set of objectives (4 to 6 is recommended) each one being an activity that can be carried out by the student within the project period resulting in a measurable outcome that can be expressed in a document. The expression of scope and scale may be explicitly stated or may be implicit in the way the aim and objectives are worded. Markers should also be aware that working through the early stages of problem definition and Application Outline all contribute to an expression of scope but the scale may be expressed later in the Research Design itself.

Section C - Marks for Project Primary Data Research and Outcome Generation

5. Detailed requirements collection plan based on proposal

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers should look for a rational and thoughtful consideration of the Requirement Gathering process focused on obtaining sufficient information to build the intended application and resolve the stated problem theme. In practice this implies a consideration of application functions, location of requirements data and the collection protocols that might be used. Normally in research one would expect a rationale for the choice of Research Method but for Engineering projects it is taken for granted that the method is requirements gathering. Instead one should look for a clear focus on constructing a feasible and comprehensive requirements document based on the application outline. Furthermore, markers need to feel confident that the student understands the distinction between Requirement Gathering as a Research Method and the collection protocols used within it.

6. Analysis of requirements: functional, performance, technical and usability

Reference: Workbook 3 section 3.5.1 (example) and Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6

Markers must look for a clear Application Proposal and a requirements catalogue. Here one needs to see a discussion of the requirements to ensure they are credible (realistic), comprehensive, complete and stakeholders have been considered. One might also usefully consider the approach that was taken to gain them and whether they are of the form of strategic, tactical or operational.

7. Presentation, analysis and discussion of the design
Reference: Workbook 9 sections 9.6.5 and 9.6.6 and Workbook 7 section 7.9
Marks are awarded here for clear evidence that the student has taken the requirements obtained earlier in the project and processed them to get a suitable design. Therefore, markers must be able to see a clear link from requirements to design and where necessary observe how the requirements were processed. Markers should be wary of processing plans that say such things as "I will look at the requirements" or "I will analyze the requirements" as these directions tell us nothing of value. The criteria used to assess the processing plan is that there must be enough detail so that if another person were presented with the same requirements they could apply the same processes and get the same or at least a very similar outcome.
8. Discussion of build process and design implementation
Reference: Workbook 7, Workbook 9 sections 9.6.5 and 9.6.6
Marks are awarded here for a rational discussion as to what architecture, components, languages and tools and so on are needed to best implement the design. This discussion may also imply the various situation constraints have to be considered as well.
9. Application testing process and results
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers must look for evidences of a testing plan and a consideration of test results. Typically the plan and results are placed in the main project document in outline form with the details in an appendix. Often students will just discuss white or black box testing or regression testing or something similar but without any actual test plans or results – in such cases marks should not be awarded as these materials are considered common knowledge at this level – however brief references to it are permitted.
10. Implementation plans
Reference: Workbook 9 sections 9.6.5 and 9.6.6
Markers should look for a comprehensive implementation plan – it need not be extensive or in minute detail but it should cover installation, user training, data conversion/loading, change over, user acceptance and hand-over.
11. Attributes of the project artefact (e.g. quality, reliability, etc)
Reference: none
The intended project application must be clearly visible and available to run directly from a disc or DVD. Markers are to award marks based on their perception of the general quality of the application if they were to put themselves in the place of a user. Assessment may then consider colour scheme, ease of use, operating instructions, presentation (does it look as if its finished), speed, etc.
Section D - Marks for Project Evaluation and Conclusions
12. Evaluation of the project outcome (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project application so generalisations are not appropriate here. The section is important as this is where one expects to find some information on what the student has learned about the problem situation and the significance of solution or partial solution they have generated. Unfortunately, in many projects this section is missing, cursory or so routine that it has nothing to do with the project application. The section is not intended for vague thoughts about the situation or application but a considered evaluation of the project application when viewed against the problem definition as stated earlier in the work and its setting. Typically, evaluation is against objectives, other existing products, using defined criteria or some form of expert evaluation coupled with any constraints that might have impacted on applicability of the outcome or its generation.
13. Evaluation of project practice (project specific)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
This section is specific to the project practice so generalisations are not appropriate. This is where one expects to find some information on what the student has learned, the way they work and the tools they used. It is often the case that students have very little idea what they did apart from being able to state vague activities such "look at" or "analyze" so without anything concrete to evaluate they resort to the routine and say "the survey process went very well" or "the UML modelling was straightforward" or else they simply ignore this form of evaluation. Evaluation of project practice is difficult because the student must ask searching questions related to process success and the notion of good and best practice based on performance criteria and simply asking 'how did I do it', 'was it successful' and 'could I or should I on reflection have done it another way' or "what were my constraints".
14. Statement of conclusions and reflections (Project Generalisations)
Reference: Workbook 9 section 9.2.4 and 9.6.7 and Table 6
In this section markers should expect to find generalisations based on the project outcome and project practice. For example, if an application was for eCommerce selling shoes it might be possible to ask what aspect of that application could be re-used to sell other product. It is permissible to consider other elements but not at the expense of the generalisations being omitted or lacking in reflective depth. However, elements such future work, features of the practice that are applicable more generally, part or all of the outcome that is useful outside its immediate setting, usefulness and availability of literature sources, relevant aspect of the course, what main lessons were learned or value-added features. Normally, if a student discusses his/her objectives here it is a good sign that they have confused evaluation and conclusions. Objectives are mostly project specific and should not therefore be discussed here but only in the evaluation.

Section E – Qualitative Assessment matrix based on University Grade Criteria

This matrix allows the marker to make a rough qualitative assessment of project work and this is characterised by a left (poor) to right (good) orientation. The matrix is designed to work with the University grade criteria and acts as summary of your assessment of the various elements and as a check that the actual mark you awarded is a fair reflection of the student's work. Once you have made this assessment you need not comment any further in section F on the various points unless it is to add a note of clarification or to indicate that your assessment is conditional. For example, if you assess spelling and grammar as "was full of mistakes" there is little point in repeating that as a free comment however, if conclude that the report structure is "very poor" you might want to say why that is so.

If the comment row is for whatever reason not applicable it is customary to place a cross in the row number but it is not necessary to explain why this is so in section F.

Section F – Marker's Critical Comments

In this section it is expected that you will provide a critical reflection that summarises your view of the project as a whole after the marking has been completed. In arriving at such a view one needs to be mindful of the visibility of the project outcomes and an evidential trace so that it can be seen how the outcome was generated. It is useful if you can highlight major weakness, interesting observations made by the student or other novel features of the work.

Written comment is especially welcome and useful when the mark is either >69% or <40% to give the Unit Assessment Board some indication of why your thought the work was either in these ranges. When you explain your thinking here it must be based solely on the work presented and not on such things as "good worker", "always tries hard", "a dedicated student", "never gives up" or other personal observation of that kind. Of course the attitude of the student is important but that is not what is being assessed. The role of assessment is related to the Learning Outcomes for the project Unit expressed in the overall quality of the work produced.

Section G – Note here elements you want brought to the attention of the External Examiners

This section must be completed whenever you feel there is something **exceptional** you want brought to the attention of the External Examiner as indicated in the header lines to the mark form. Typically, a marker will refer to the External exceptional pieces of work, work where there is some question as to whether it meets the course criteria (for example instead of submitting a project on some aspect of IT they submit one on marketing) or where a matter principle is at stake – for example one might have a project which is very good except that the English is very poor.

Markers must note that refers should be exceptional and when it is done one is only to seek opinion. It is not permitted to refer to the External Examiners a project for a decision.

13. WORKBOOK 13 – FORM: PROJECT MARKING RECONCILIATION

The form shown below is included for reference only so that you can see how your project will be marked.

Project Mark Reconciliation Form		Final Agreed Mark (%)	
Name of Student			
Brief Project Title			
Name: Supervisor			
Name: Second Marker			
Name: 3rd Marker			
<p>Cause – in this box, describe, for each applicable section, why the marking disagreement occurred.</p> <p>Rationale – in this box, If a mark can be agreed, explain the rationale used to reach agreement. Please note that it is only necessary to agree the total mark for each section not individual category marks.</p> <p>Irreconcilable - If you cannot agree a mark leave rationale blank and it will be filled in by a third marker who will place a tick in the small square box.</p>			
Section A - Marks for Planning and Preparation		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			
Section B - Marks for Project Introduction		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			
Section C - Marks for Project Primary Research and Outcome Generation		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			
Section D - Marks for Project Evaluation and Conclusions		Agreed New Sub-Total	
Cause			
Rationale			
<input type="checkbox"/>			

14. WORKBOOK 14 – SUPERVISION AND MARKING GENERAL GUIDANCE NOTES

1. **Presented Work** - Marker's are reminded that any marks awarded must be solely based on the assessment of work presented within the mark categories listed on the mark forms. It is not permitted to award marks for "hard worker" or "tried very hard" or "was a good student" or any similar observation as there are no relevant mark categories and this kind of criteria is almost impossible to evidence.

When an Engineering artefact is presented it should be viewed in action to ascertain the mark for "Attributes of the Project Artefact". The copy of the application supplied on disc must be complete and run on any standard Windows based PC with a simple click or double click on an appropriate name or icon visible in the disc directory. If this is not the case then markers must assume that there is no evidence for the application and set the mark accordingly.

2. **Word Count** – on the project submission form there is a space for a word count (excluding appendices) and if this is exceeded then it is indicative of a deliberate attempt to go beyond recommendations and you may therefore find that it leads to laboured descriptions or inclusion of irrelevant material in the project document and you should therefore mark accordingly.
3. **Structure** – mark categories do not necessarily represent chapters in a project document and so Marker's need to be aware that a particular project may be structured in a way that does not correspond to the sequence presented on the mark forms (though it is recommended to do this when possible). However, all the elements on the marking form must be visible in the work presented.

Although it is recommended that the mark form sequences be followed in the project document that does not mean that there has to be a chapter for each mark category. Students, therefore, should be encouraged to merge sections in order to produce a concise document. For example, it is perfectly possible and reasonable to merge the two evaluation sections and conclusions into one chapter as long as the relevant mark elements are still visible.

4. **Appropriateness** - any work presented must be within the prescribed subject area for the course. If a marker suspects that this is not the case then they should consult with the relevant course leader for clarification. In such accepted cases markers must regard the primary data and its processing as not being appropriate and mark with that in mind.
5. **Evidence** - the project report or appendix must contain sufficient evidence that the core project research work has been done (not the literature review). That is, in the case of study project a marker must be able to see the primary data collection appropriately presented (usually in an appendix). In the case of Engineering projects it must be possible to see a suitable requirement document or catalogue (possibly in the appendix). Once the primary data is visible then it must also be possible to see how that data was transformed into the intended project outcome.
6. **Literature Support** - when marking Literature Reviews their content must be seen to be focused on the topic area and address clearly the associated problem theme without any irrelevant material with the intention of offering a concise discourse that is focused, relevant, authored, measured, evaluatory and expressed as a dialogue. (see section 5.1)
7. **Grade tables** - markers must be aware of the criteria associated with awarding a given overall mark as they may be required to justify it to the UAB in terms of the criteria stated in the table shown below.
8. **Process** – when marking it is important that the process used to get an outcome by the student is visible in the project document. In practice this means that it is possible to perform the following trace: presenting problem, discussion of how problem might be resolved, suggested form of project outcome, research design and execution, generation of stated outcome, evaluation and conclusions – viz:

Engineering – typically, the process starts with a business related or technical problem theme leading to a research plan for the collection and discussion of requirements and their transformation into a suitable design and associated architecture. From this there should follow a build, implement and testing process with the whole project completed with suitable project specific evaluations and conclusions containing generalisations.

Study – typically, the process starts with a business or strategic IT related problem theme leading to a research plan for the collection and discussion of primary data and its transformation into an outcome that would resolve or go some way to resolving the stated problem theme. The whole

project is then completed with suitable project specific evaluations and conclusions containing generalisations.

Marks	Master's Level Grade Criteria
70 – 100	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Excellent work - able to express an original reasoned argument in a lucid manner by reviewing & critiquing a wide range of material. Original, critical thinking based on outstanding insight, knowledge & understanding of material. Material contributes to current understanding & is of potentially publishable quality in terms of presentation and content ▪ Wide reaching research showing breadth & depth of sources
60 – 69	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Clear, balanced coherent critical & rigorous analysis of the subject matter. Detailed understanding of knowledge & theory expressed with clarity ▪ Extensive use of relevant & current literature to view topic in perspective, analyse context & develop new explanations and theories
50 – 59	<p>As below plus:</p> <ul style="list-style-type: none"> ▪ Detailed review and grasp of pertinent issues & a critical contextual overview of the literature. Thorough knowledge of theory and methods & uses this to underpin arguments and conclusions ▪ Confidence in understanding and using literature
40 – 49	<ul style="list-style-type: none"> ▪ Demonstrates grasp of key concepts & an ability to develop & support an argument in a predominately descriptive way with valid conclusions draw from the research ▪ Familiarity with key literature which is cited and presented according to convention ▪ Logical & clear structure, well-organised with good use of language and supporting material
0 – 39	<p>FAIL – Some knowledge of relevant concepts & literature but significant gaps in understanding and/or knowledge. Little attempt at evaluation, conclusions vague, ambiguous & not based on researched material. Limited or inappropriate research. Deficits in length, structure, presentation &/or prose.</p>

15. WORKBOOK 15 – FORM: UNIT FEEDBACK REPORT

This form may be used by you to feedback to the University your experiences in the courses. It is normally sent to your tutor at the end of the course.

Unit Level Feedback – Delivery Evaluation for Online Units						FF.2.3	Page 1 of 1
This student feedback questionnaire is intended to help students provide constructive feedback to the unit lecturer.							
Student Name (Optional)						Cohort	
Unit Name							
Lecturer							
Q	Good					Place a ✓ to rate each factor from strongly disagree to strongly agree in one of the 5 boxes	
1						Chat sessions started promptly.	
2						Char sessions were structured usefully for learning.	
3						Chat content helped my understanding	
4						Chat Tutor handled student questions sympathetically	
5						Chat Tutor used helpful examples where necessary	
6						Chat Tutor answered session questions in a helpful manner.	
7						Chat sessions stimulated me to think beyond the material delivered.	
8						Chat topics were often related to real-world situations.	
9						Chat Tutor encouraged students to participate during the session.	
10						The Tutor was expert in the subject area.	
11						The written notes provided were helpful to my learning.	
12						The study pack Workbooks were helpful in my assessment preparation.	
13						The 5 milestone tests helped me to confirm my knowledge.	
14						Tutor responded in a timely fashion to discussion board questions.	
15						Tutor responded in a timely to my email communications.	
16						Tutor was sensitive to the problems of individual students.	
17						The assessed work stimulated me to think deeply about my project.	
18						Feedback on my progress was available.	
19						The topic approval process helped me think clearly about my project.	
20						Written assignment specifications were clear.	
						For Official Use Only	
General Comments:							

Exercise 004b.01a – Finding a Basic Activity Word Spotlight

This exercise and example sheet takes you through the whole of the research process. I have summarised all the things you need to know and provided some partial and some full samples. You must go to the partial example and complete them by looking at various elements and using them to write a research question. I will NOT be providing answers for all these samples (you will be doing that in discussion) and they are there for you to practice and use in your groups. Please don't avoid the work, you MUST get to a stage of knowing that what you have written is correct – if you don't know it's correct then you are not ready to do your own.

To start this off complete one or more of the examples and post the resultant Research Question into the discussion Board where I and others can comment.

Basic Activity Word – this entry will give a concise definition of the word
WARNING – in the Research Methods course the following key words have a defined meaning and you MUST study the relevant entries in the workbook. DO NOT assume that you know what these mean else you are likely to get into considerable difficulties.
Problem – this must define a single core problem for which you are going to find a solution route
Target – these are the effects that will be evident in the real world if the problem can be solved. It is permissible to list more than one effect but it is best to look for the principle one.
Outcome – this is the object you will generate as the final product of your MSc project. Possible outcomes are characterised by nouns so might be: reports, models, frameworks, policies, strategies, position papers, reviews, procedure description, best practice descriptions, dictionaries, lexicons, concordances, protocols, dossier, diagrams, charts, plans, etc.
Actor - It is normal when you define your outcome to say who the actor or actors are (meaning persons) who will use your defined outcome and to show that its use by them leads to the target effects
Activity and Data Spotlight – this is just about focusing on exactly the primary data that you need and nothing else. There are two parts really here: the activity: account for, analyses, collate and so on and the spotlight, the place where the data comes from
Research Question – this is a sentence expressed as a lucid question that connects the various features and expresses the direction of your research and summarises your whole project. The 6 elements are: interrogative, outcome, actor, problem, target and spotlight (data) - IO-APTS. The acronym IO-APTS is the correct order of these features in a sentence when the interrogative is “what” but for other interrogatives the order of features may need to change if you are to produce a valid sentence in English. Possible interrogatives are: Whose, who, whom, what, which, where, whence, whither, when, how, why, wherefore, does/is, s/are, and can.
Research Method – choosing a method will depend on many factors such as: context, time available, skills available, practicalities, access, reason for the study, what kind of outcome you want, cost, nature of the study quantitative/qualitative, scale, control, and sensitivity of the data and so on. In this set of examples I choose a Research Method based largely on the basic purpose of the study. Basic purpose is usually assumed to provide as an outcome one of the following forms: express an understanding, an exploration, a description, an explanation, an improvement suggestion, build something or prove something. Common Methods and typical uses are: Case Studies – useful when trying to understand a situation or practice Vignettes - useful for exploring a situation in order to illustrate its major features Action Research – useful when it is desirable to improve a situation by working within it Experiments – useful when one is trying to prove or more usually indicate the truth of some proposition Quasi-Experiments – as for experiments but the experiment can only be simulated Surveys – useful when trying to describe a situation or effect Biographies/History – useful when one wants to explore a situation in order to replicates it or improve it Grounded Theory – useful when the area under study is barely understood but needs to be explored Ethnography – useful when one wants to describe a situation of some kind involving behaviour Requirements Gathering – useful when one wishes to build a real world object
Collection Protocol – this describes the means by which the primary data is actually collected: interview, questionnaire, observation, role playing, seminar, focus groups, document or record searching etc
Pre-Processing – this describes how the primary data in its raw collected form is processed into a structured collection of some kind.
Outcome Processing – this describes how the structured primary data collection is used to generate the intended outcome.

Account for - Explain and clarify something by giving reasons
Problem – inventory discrepancies leading to additional costs and delivery delays.
Target – reduced inventory cost and assured delivery times to customers
Outcome – revised inventory processes model
Actor – manager or managers responsible for inventory systems
Activity and Data Spotlight – to account for (activity) inventory discrepancies caused by current procedures (spotlight)
Research Question – what (interrogative) revised inventory processes model (outcome) can be used by inventory managers (actors) to make changes to the current system in order to reduce or eliminate inventory losses (problem) so that costs are reduced and customer delivery times assured (target) by exploring and illustrating features of working practices in the current inventory system that might account for inventory discrepancies (spotlight).
Research Method – in this case I am basically exploring this problem situation looking for illustrations of why discrepancies occur so that leads me to think that the method of Vignettes is the most suitable research model here.
Collection Protocol – record searching coupled with interviews .
Pre-Processing – this raw primary data collection will be pre-processed in order to structure the collection into the form of a catalogue of processes description each with a weakness assessment.
Outcome Processing – the catalogue produced in the pre-processing stage will be used to generate the outcome of a set of revised inventory processes using the company best practice model. This outcome will then be used to reform the way the inventory is managed and in so doing allow managers to generate the target of reduced inventory losses, reduced costs and assured delivery times.

Analyse - Resolve something into its component part, or examine critically and minutely.
Problem – delays and errors in generating audit request data
Target – reducing the time taken to generate the requested data and at the same time improve its accuracy.
Outcome – a report with recommendations
Actor - management
Activity Data Spotlight – to analyse (activity) the process used to extract data from the accounting systems for audit requests (spotlight).
Research Question – what (interrogative) recommendations (outcome) can be generated and used by management (actors) to plan for the enhancement of current audit request procedures in order to ensure that delays and inaccuracies (problem) are eliminated (target) by a close analysis the audit request protocols (spotlight).
Research Method – here my primary need is to understand the audit request process and so I will treat each request as a small case study .
Collection Protocol – a form of role playing will be used to duplicated and simulate the request
Pre-processing – the extracted audit data and the request will be pre-processed into a matrix which will be formed by listing the request, process used, data sensitivity, classification and auditors assessment of data quality...
Outcome Processing – using a process model the data will be used to form a mapping of requests to consequence and hence derive tips with recommendations to management on the effectiveness of current audit processes. This outcome will then be used by management to make an informed decision on the way audit request are handled in the future and in so doing generate the target of reducing the time taken to generate the requested data and at the same time improve its accuracy.

					<p>– This is best thought of as something like forming an opinion about something. It might be quite simple such as forming an opinion as to whether something is good or bad but more often that not it's about forming an opinion about something after assessment or evaluation with regard to what can be done - so we might appraise whether a process for example should be left unchanged, modified or made redundant.</p>
					<p>– poor IT staff utilization as is apparent in increasing staff cost and high consultancy fees.</p>
					<p>– increased management awareness on current IT staff utilization practices</p>
					<p>– an assessment report on cost savings and other benefits that might accrue from a better utilization of existing staff.</p>
					<p>- departmental managers</p>
day	1	1	1	1	<p>(activity) the staff utilization practices with regard to IT technicians (spotlight)</p>
oi					<p>– How can (interrogative) effective utilization of IT staff (problem) be achieved after an appraisal of staff utilization practices (spotlight) in order to generate an assessment report (outcome) for use by departmental managers (actor) to aid and inform them in job distributions so that a reduction in costs can be achieved based on a maximization of existing staff's abilities (target)?</p>
					<p>– my basic need here is to develop the process so that leads me to believe that this method is most likely to give me a suitable research model.</p>
bt	Poi	1	1	1	<p>looking for example of utilization and how they were decided upon. It may be necessary to supplement this with literature.</p>
					<p>– the raw primary data will be grouped into groups based on a manager's assessment of each employee focused on the current company standard payroll scales.</p>
gi					<p>– the grouped utilization practices and managers assessment will be analysed using an in-house workflow model to derive estimate of possible cost savings and other benefits that might accrue from a better utilization of existing staff. This outcome will then be used to brief departmental managers in order that target of increased management awareness on current IT staff utilization practices is achieved in preparation for the bi-annual leadership meeting where this problem theme will be discussed.</p>

					<p>– Determine the value of something. Similar to evaluation but it is often useful to think of evaluation as a qualitative process and assessment as a quantitative one.</p>
					<p>– suspected under use of the new CRM system because some processes may have been inadvertently duplicated within the vestigial manual elements from the old system.</p>
					<p>– increased effectiveness centred on full use of the CRM system</p>
					<p>– list and rationale for the removal of suspected redundant processes</p>
					<p>– area managers</p>
day	1	1	1	1	<p>(activity) the impact of effectively duplicate processes (spotlight) on the overall operation of the CRM systems in relation to potential cost saving.</p>
oi					<p>– What (interrogative) rationale (outcome) can be found for the removal effectively redundant manual processes (problem) which can be used by area managers to reconfigure their CRM systems to increase its effectiveness and hence raise business productivity and reduce costs (target) by a assessment of the impact of suspected redundant processes on work flows (spotlight).</p>
					<p>– there are expected to many processes involved and it seems appropriate here to use a model because I need to understand why these duplicate processes co-exist.</p>
bt	Poi	1	1	1	<p>to obtain the processes followed up with the process assisted by</p>
gi					<p>– the various duplicate or almost duplicate processes will be analysed by their expected impact on overall system efficiency using a standard model based on the factors: utility, process cost, training commitment,</p>
gi					<p>– to obtain the outcome of the removal suspected redundant processes that can be removed from the system each process will be reviewed by a seminar panel of relevant managers. This outcome will then be used by area managers to decide what vestigial processes can safely be removed without affecting company throughput and in this way generate target of increased effectiveness centred on the full use of the new CRM system.</p>

	①	- This means to create an ordered collection of some sort where there is a logical order and the essence of the task is to enumerate and describe
	②	- variable tele-worker productivity in software development
	③	- assured worker productivity levels
	④	- worker stress report
	⑤	- product project managers
day 1	⑥	(activity) the stress effects imposed on tele-workers (spotlight) in a fast moving software development market....
goal	⑦	- How can (interrogative) managers gain assured productivity levels (problem and target) from tele-workers in software projects (spotlight) by commissioning a stress report (outcome) which will later be used by product project managers (actors) to plan an effective and balanced work schedule.
idea	⑧	- here I want to focus on this area so I am going to focus on and trace worker activities.
point	⑨	will be used to look for interesting or unusual candidate work activities by means of a focus on and trace their CV and
	⑩	- the interview and document data be processed using common text processing ideas to classify and prioritise the main stress effects and presented as standardised sheets.
goal	⑪	- based on the biographies a worker stress report will be prepared for management with an assessment of possible productivity impacts. This outcome will then be used by product project managers to balance workloads based on the various stress factors uncovered in the report and hence generate that of assured worker productivity level.

	①	- This is very simple as all one does is to identify the data and literally collect it as you see it. So if I were looking for SPAM instances then as soon as I find one I just file the whole SPAM email away for later processing.
	②	- customer complaints about delays in resolving problem via the help desk
	③	-
	④	-
	⑤	-
day 1	⑥	- will be based on (activity) help desk work requests and their associated actions (spotlight) that have been delayed for more the 48 hours...
goal	⑦	-
idea	⑧	- this is a potentially large population so for practical reasons I will use the format as I feel I am mainly trying to describe this situation.
point	⑨	- effectively the protocol where we one extract the above information from the help desk log.
	⑩	- classify the work requests into by: operative, system and action with a final assessment by the relevant manager of the main cause of the delay.
goal	⑪	- the prioritised list will be used to generate a plan to deal with identified common causes of delay with a view to revising the current help desk work model. This outcome will then be used by the systems team to focus the help-desk re-building process and hence it is hoped generate that of a more efficient and reliable service.

	Op	- Look for similarities between one or more things.
	relP	- apparent mismatches between company needs and programming staff recruited
	ga	-
	un	-
	ot	-
gi l \$a	yt Mi	- to op (activity) IT recruitment guidelines with current company tasks (spotlight) and their implementations
oi	Co	-
	Mo	- since this is largely looking at what might be called historical data it seems worthwhile to use h as the most suitable method
oi	btPn	- the essential task here is by a process as one compares the existing guidelines with the defined task specifications.
	dyasp	- none as a suitable I may be constructed at the collection stage by just using the guideline indices.
gi	un	- the list will be processed to obtain a set of recommendations on a revised set of guidelines that better reflect company needs as found in the required tasks. The principle processing mechanism will be to use the existing task cost structures and the company staffing policy to arrive at the result. This outcome will then be used by team leaders and heads of department to focus their staffing needs in software development into an accurate and lucid job descriptions and hence generate the list of reduced recruitment costs and accurate selection of new staff to fit the required job profiles.

	eOp	- similar to list but here the implications is your are searching many sources and having to make decisions in the process
	relP	-
	ga	-
	un	-
	ot	-
gi l \$a	yt Mi	- to op el i (activity)
oi	Co	-
	Mo	-
btPoi	te l	-
	dyasp	-
gi	un	-

bi	Look for differences between one or more things.
Sal	- apparent mismatches between company needs and programming staff recruited
yt	-
ni	-
At	-
bi Sal	(activity) IT re recruitment guidelines with current company tasks (spotlight)
yt ni	-
At	- since this is largely looking at what might be called historical data it seems worthwhile to use as the most suitable method
bi Sal	- the essential task here is by a process as one contrast the existing guidelines with the defined task specifications.
yt ni	- none as a suitable may be constructed at the collection stage by just using the guideline indices.
At	- the list will be processed to obtain a set on a revised set that better reflect company needs as found in the required tasks. The principle processing mechanism will be to use the existing task cost structures and the company staffing policy to arrive at the new guidelines. This outcome will then be used by team leaders and heads of department to focus their staffing needs in software development into an accurate and lucid job description and hence generate the of reduced recruitment costs and accurate selection of new staff to fit the required job profiles.

bi	- Make a judgement, backed by a discussion of the evidence or reasoning involved, about the merits of theories, opinions,...
Sal	- apparent bottlenecks in the repayment system causing customer complaints and miss-payments
yt	-
ni	-
At	-
bi Sal	- to form (activity) of each stage of the current repayment work flow (spotlight) with regard to IT usage....
yt ni	-
At	- as my main aim here is to improve the flow in some way I have decided to
bi Sal	based on the workflow definitions will be the main collection vehicle here.
yt ni	- this will look for outliers and clusters in the critique summaries and form them into in a prioritised order.
At	- this will be in two stages. The first stage will look at outliers as they are normally indicative of underlying problems themes. The second stage will look at clusters as this implies similarity and that may point to where future IT deployments may best be sited. These two sections will then be used to generate the outcome of that can be used by finance managers to continually monitor the repayment cycle in the future and hence generate that of functional repayment cycle which is reliable and verifiable

bi	- State the exact meaning you are attaching to a word, phrase, idea, process etc
RP	- apparent transaction losses
ga	-
de	-
de	-
bi \$a	– do it (activity) the state of each logged transaction within the scope of the current network transmission protocol (spotlight)
oi	-
de	- this study will look at a large number of transactions and the essential method is therefore
btPoi	- transactions data will be extracted automatically from the log by means of a software application. The software will also tag the various transaction types according to metrics defined in the literature to form a set of transaction definitions.
gisp	- none as a structured collection with be available via the automate collection stage
gisp	- the processing will automatically scale the data and display it in graphical form and of particular interest is transactions that might be regarded as outliers as they may be anomalous and point to processing sequences or other error types. Once the outliers are known it will be possible to produce as an outcome a set of verifiable metrics that can be used to predict which transactions are likely to cause process cycle difficulties and hence remedies can be sought in order to achieve that of reduced transaction losses.

bi	- This may be used freely to describe in detail situations, events, opinions, feelings and so on.
RP	- lack of trust in security checking
ga	-
de	-
de	-
bi \$a	– do it (activity) differences in network penetration test results carried out over several test periods (spotlight).
oi	-
de	- since we are essentially looking at historical data the method used will be used
btPoi	– the various discrepancies uncovered will be classified into severity levels and presented in a format with administrator comments and a description of why it might have been missed on the previous test cycle.
gisp	– Using the structured primary data set and methods used in the testing suite attempts will be made to identify test scope factors that may have allowed faults to be overlooked and hence expose the network to unnecessary risk and hence generate the outcome of a revised testing suite so as to achieve that of a security assured network.

et al	self ID	- Look for elements that would clearly differentiate between two or more things
mbP		- poor IT utilization amongst middle level managers
ga		-
de		-
ok		-
day m i A		- to explore the cultural milieu in which managers of an organisation exist various cultural elements (spotlight) that are present.
oi Coe		-
how		- in this I feel I need to immerse myself in the day to day life of managers in order to see how that milieu might point to how IT training might be used by them and this makes me think of the research method of E
bt Poi t C		- this is a slightly sensitive area so it seem best to use based on spending long sessions within the managers department coupled with informal
apiesP		- the raw primary data will be in the form of a mixture of short and long notes plus some formal interview transcripts as well as some video and photographic information. With the rich information base an attempt will be made to extract typical ethnographic elements such as: behaviours, structures, functions, roles, politics and communication styles. The extracted data will be carefully organised into categories within these categories.
gisa		- using the structured primary data collection I will attempt to match cultural themes found within a manager's department with a training mode that might be best suited for that culture. The basis of the matching will be to use the 5 stage learning model developed by Garlick (1999) so that in essence we link learning progression to its cultural suitability. The outcome will be presented as an IT training plan and used by the manager's forum to adjust their personal training portfolio so as to achieve the goal of higher IT utilization leading to more effective middle level management.

SD	- Explain something by giving two sides of the argument
NP	- non IT personnel are reluctant to engage in computer user training
GA	-
MA	-
DA	-
DAyt iA	- said (activity) the function of IT training for non-IT personnel (spotlight).
oi Coe	-
MoCo	- this is essential and it therefore seems best given the wide diversity of opinion that is likely to emerge to use the method.
bt Poi tC	- a presentation will be made in sessions and this will be followed by a discussion. Although this is a survey I have chosen this method as I want it to be a learning experience for all involved as well so in effect I will be looking to see if the seminar assists in forming opinions.
ArgiP	- the seminar discussion notes will be structured by looking for the usual text processing elements such as: common threads, outliers, labelling, etc and formed into a report.
giCo	- the outcome is to provide a vital insight into the company and this will be generated by looking at the elements identified in pre-processing and knowing these have emerged from a sample the attempt will be made to say what it might mean for the whole company - can it apply to the whole company, is there some important element in this theme that has much wider implications, is there a principle that can be established, can I construct a theory and so on. The outcome will be presented to company and training management with a view to informing them of the general feelings and desires of the wider non-IT workforce so that they can be taken into account in the construction of future training plans and personal training portfolios that better fit with worker needs and aspirations

		- In some cases one might want to look at events or people or processes in order to form an evaluation and that collection of (usually) small evaluations form our primary data.
		– unemployed people's disappointment in their inability to locate an appropriate job
		–
		–
		–
bi l \$ ad y t i i		(activity) the elements functioning negatively and positively in job searches (spotlight).
oi		–
Mode	de	– I am looking for the various factors that might be involved in job searching. Many of these will of course be well known such as qualification or skills but there may be many other that are not so obvious such as ethnicity, age, sexual orientation to name but a few. With this in mind I intend to explore this area looking for suitable illustrations of these factors and how they acted negatively or positively with regard to obtaining employment and so I feel the method of V is most likely to be valuable here.
bt Poi	te l	– My procedure will involve jobless 18-25 year olds (plenty can be found in job centres) in a defined inner city to collect illustrations of successful and unsuccessful job searches.
		– the interview transcripts will contain what amounts to suitable illustrations so these will be extracted and standardised based on a simple job seeker profile of successful and unsuccessful job searches illustrations.
gi		– using the illustration portfolio will be devised that when coupled with a standard job
el i	tp	can be used to enhance a web search for suitable employment opportunities. The outcome of the and I will be made available to job seekers and web job search system providers in order that that of effective and satisfying web searches can be achieved.

		- Look carefully at the details of an argument, theory, or plan etc
		– frustration at the apparent time wasted on electronic correspondence
		–
		–
		–
bi l \$ ad y t i i		- to (activity) the various activities involved in the electronic correspondence process (spotlight) such as e-mail, fax, documents, photos, electronic forms, document and imaging process, accessing of images, routing/delegation functions according to the work flow process.
oi		–
Mode		– there are several main areas and I need to form a of the various technologies and processes so I will use the method and treat each communication area as a case study.
bt Poi	te l	– in this study I want to collect various communications samples and the practices associated with them in several areas and it seem best to do this by a series of with selected personnel from various levels in the company.
		– the collection phase will generate a large raw data set consisting of artefacts (samples provided in the interviews) and activity descriptions. It seems best therefore to organise these into a communication area/activity linked to an artefact sample.
gi		– I think it best to process the matrix and catalogue to derive some suggested best practice description in the various areas and then by means of arrive at agreement on what can be called best practice and hence construct an
oi	of t p e e t a b	in electronic communication and this can be used by individuals and training management to help ensure that of communication being viable, efficient and satisfying to participants.

na	- this is about saying why something is. So one can describe an event but also explain why it occurred
na	- serious concerns in some departments over impacts on working practices of a proposed new land registry application
na	-
na	-
na	-
gi \$a	na (activity) possible impact effects of a new land registry application system and database (spotlight) in common areas such as: cost, performance, user acceptance, etc
oi	-
na	- the suggested method here is an extended as the system itself is quite extensive
btPoi	- there will be three main mechanisms to establish expected benefits and then
si	to establish the consequences in the various areas
na	- the observations and focus group information will be compiled under various headings using a standardised format but will in large part be based on the companies stress model as the main aim here is to assess impacts but largely those will be people based impacts. The chosen method is to draw one based on the catalogued information so that various perceptions can be shared and as a final step carry out another where the pictures are examined and discussed.
gi	- the intended outcome will be generated based on a careful analysis of the catalogue produced in pre-processing. From the catalogue and the final focus group information a comprehensive will be compiled that can be used to assist in planning by management for the implementation of the new system and hence achieve that of alleviating genuine personnel concerns and preparing the organisation for a smooth transition.

na	- You can use this word but we are always exploring so it must be used with care. Typically, in these cases one starts with a model of some kind and uses that to inform the exploration process. For example, we might have a theoretical process map and we use it to explore various working processes to see if we can find flaws or weaknesses and then those descriptions of flaws or weaknesses become out primary data.
na	- loss of market potential for my company
na	-
na	-
na	-
gi \$a	na (activity) the company business profile with regard to its fit within the modern global economy and the use of the Internet and eMarketing/eCommerce (spotlight)
oi	-
na	- this and in this case it seem best to think of the whole company as one area and the need to clearly its business profile.
btPoi	- there is potentially a lot of information here and it might be in diverse places including just in people minds so it seems best to it coupled and then follow this up by sessions to share perceptions via Rich Pictures.
na	- The various interview transcripts and document extracts will be examined using normal text processing ideas to produce a detailed (products, policies, structure, finance, Issues, IT infrastructure, etc) supplemented by feedback from the seminar sessions.
gi	- armed with the full business description and Rich Pictures there will be an open discussion with consultants about creating an outcome for an eMarketing/eCommerce outlet with that of increasing the company's market potential based on using Porters 5 forces model as a starting point.

etarts	I	– Here one is trying to find a way to expresses in a very pointed way some situation or thing. So one might identify an instance of SPAM and then illustrate why it might be harmful so adding poignancy to the example you have extracted. Mostly, it is best to think of illustration as a way of giving an example but in that example you want to make just one clear point.
etP		– expressed dissatisfaction with the quality of delivery within a training organisation
et		–
et		–
et		–
gi \$a	et \$a	et \$a (activity) how a student's acceptance and satisfaction in a training course (spotlight) are affected by the various technologies that might be used.
oi		–
et		– this is a new area and I am not sure what sort of things will emerges so it is therefore largely
et		study and since I am aiming to find various factors that might be significant I think
et		method is the most appropriate.
et		– in this case I am looking for examples or illustrations of the various factors in action. It therefore seems appropriate to use
et		of participation activities that occur during training.
et		– the raw primary data will be in the form of simple illustrations of training activities and an assessments of the technology effects that were observed. This raw data will be processed to find a common
et		of illustrations that explain technology acceptance and satisfaction levels and each illustration will effectively define a training factor.
et		– using the catalogue of illustration and named factors a training
et		will be constructed that maximises both satisfaction and acceptance. This will be accomplished by using the standard model features and outline course learning objectives. The outcome will be used by trainers to re-model all course offerings and hence achieve
et		of higher satisfaction levels in our course provision.

et	I	– The essence here is that one is typically observing something to describe it but also to find some meaning in what is being done. This is often used when looking at social groups or situations where it is not always obvious why certain actions occur
etP		– getting more value out of POS systems
et		–
et		–
et		–
gi \$a	et \$a	– to be
oi		–
et		– given the large number of potential sample points here it seem obvious that
et		is the only feasible choice
et		– the protocol will be a survey of customers by means
et		to obtain data such as average age of buyer, degree of satisfaction, service speed etc. To balance this I will also obtain from the client such things as increase in perceived business value, improvements in customer relations, kiosk usage statistics etc.
et		– the interview data will be processed using the
et		methods with some
et		and all this data will be structured into
et		with the various factors identified during text processing – one matrix from a customer viewpoint and another from the retailer viewpoint.
et		– once the matrices and statistics are available I will construct
et		on the efficacy of this enhanced form of POS using the PESTLE (Political, Economic, Sociological, Technological, Legal and Environmental) model of analysis. This report will be useful to mangers contemplating this technology as it may help in pinpointing what conditions within the market place must exist for it to be successful and hence lead to
et		of getting more return on the POS systems.

		- Show adequate grounds for decisions and conclusions and answer the main objections likely to be made about them.
1.1	1.1.1	- suggested productivity gains in upgrading to MS Vista
1.1	1.1.2	-
1.1	1.1.3	-
1.1	1.1.4	-
1.1	1.1.5	- to attempt to (activity) a new function set (spotlight) based in expected productivity gains
1.1	1.1.6	-
1.1	1.1.7	- my basic aim here is to indicate (it is not possible to prove) the viability of productivity gains from an upgrade to Vista. It follows, that the essential method here is my means of a sample because it is not feasible to install Vista on the live environment since that would imply the decision to upgrade has effectively been made. It follows that for testing to be feasible any possibly justifications must be made in a simulated environment.
1.1	1.1.8	- the means here is a pilot based on a series of Vista function tests. To carry out the tests a series of known common tasks will be formulated covering general topics such as searching, surfing, organisation (of directories and files), ..., and products based on covering Word, Excel and PowerPoint. The process will be to use the series of common tasks as part of a training exercise in Vista with several staff recruited to carry this out. The recorded data will be exercise timings, accuracy achieved and a reflective diary kept by each participant coupled with the participant and observed function justification (why it might be useful or more useful than that available currently)
1.1	1.1.9	- this will be all functions tested and with various statistical calculations attached. The reflective diaries will be scanned on each function. This will be structured and ordered by function.
1.1	1.1.10	- the catalogued justification report will be analysed from three viewpoints: the first will be utility (how well did the function perform), likeability (how well was it received by participants) and potential cost benefits in terms of productivity in order to generate an outcome to management. This outcome can then be used to gain the support of an informed management on the expected gains/losses of the proposed upgrade.

		- This is often a neat way of dealing with some types of data where you think there is a relation but the relation itself is not known with any certainty. One often finds this kind of activity evidences in a matrix formulation or representation.
1.1	1.1.1	- inappropriate user behaviour in the use of their work based PC systems and networks leading to various undesirable side effect such as loss of bandwidth, virus infection, risk exposure etc.
1.1	1.1.2	-
1.1	1.1.3	-
1.1	1.1.4	-
1.1	1.1.5	- no I (activity) a security violation with a particular user behaviour (spotlight) - that will generate a primary data item (implicit here is that we also need a description of each violation and user behaviour).
1.1	1.1.6	-
1.1	1.1.7	- the basic method here is to use a log instrument as these inappropriate user behaviours are thought to be widespread in the organisation and there is therefore a need to monitor these actions.
1.1	1.1.8	- search and extract violations descriptions from the log using a text processing tool. This is a sensitive area and one is unlikely to get good data by any direct means. However, it will be used to explore user behaviours in general.
1.1	1.1.9	- the violation descriptions will be examined in a meeting with experts to establish the behaviours that caused the violation. To do this a matrix of violations linked to user behaviour is formed with a violation severity rating based on violation extent: local to department, local to PC, local to a particular system, local to the intranet or global to the company. The interview transcripts will be summarised using normal document extraction methods and presented to inform seminar participants
1.1	1.1.10	- I need not to use the prioritised matrix to develop a plan. Therefore I might search for an appropriate BS to guide me in the process or I might use a method called PLOT - but whatever I use it has to be such that it can be repeated by another person. The whole purpose of the process is that I can then draw up a plan that might help us achieve the goal of eliminating or at least reducing these inappropriate user behaviours. The outcome will be presented to management for approval and then implemented by the IT department with appropriate training and technological means.

gi l \$ ad yt ni i A aid b (activity) an engineer's activity for each migration service (spotlight).

ni C	-
U	- this study i past records of migration activities and it is al gited them and the services they support so it seems best to think of this y s e but based on historic data with a number of migrations examined.
bt Poi t l C	- the main protocol is de gi to extract the necessary data via online status reports and these may be supplemented u veni with engineers and/or the service providers.
g i s p	- Once I have collected my primary data I will structure it as i g t e with engineer activity and migration services noting cases where migration delays occurred. The table will be organised on a key activity idea where these key activities have been established by an examination of the project plan.
g i s p	- a migration model will be used to process the categorized table to d e g e n i p of key migration activities and used by project managers to get t i g t of reducing migration project overruns.

y t b	- This might be a useful verb if you were looking for types in a study. For example, if you were looking for people who get involved in illegal downloads one might want to portray them in some way.
nt p	- SPAM is junk mail and leads to high loading on infrastructures but this study will focus on the increasing level of complaints from users ranging from simple irritation to exceeded mail box quota lock-outs.
g t	-
u	-
o t	-
gi l \$ ad yt ni i A	- y t p (activity) SPAM instances (spotlight) by extracting messages from various server logs.
ni C	-
U	- methods of SPAM prevention are well known and for this study to be interesting it needs to uncover something new that might help in the SPAM elimination battle. One such element might be to portray various kinds of SPAM perpetrators and to this end the study v e l p e SPAM messages in order to discover these portraits and so it seem best to use the ide s t g v
bt Poi t l C	- since we need to look at messages there is an inherent risk that they also carry elements such as a virus of some kind which opening the message might trigger. For this reason the SPAM message d e n i l l b e t e using a tool which I will build so that the data can be examined in a secure environment.
g i s p	- messages will be examined for common structural features such as: header, topic, sender, method of reply etc - to build up profiles of a typical SPAM message types. Once the profiles are available each message will be standardised and then presented a g l a t e . Using the catalogue a second stage of pre-processing will examine each standardised message to profile each message element: header, address, body and so on and that additional information will be added to the catalogue. The principal mechanism used here in this standardising process is the usual text processing ideas of looking for key words, labels and so on.
g i s p	- using the SPAM message catalogue and element profiles the Cambridge profile model will be used to portray senders: introduction, personal needs, interests, skills, comparison with other similar profiles, message and profile match, conflicting indicators and message offering. These portrayals will be placed i g l a t e of SPAM perpetrators with commentary and used to get t i g t of informed users and also used by system managers as a guide to building SPAM secure systems.

aim	- Give a concise and lucid explanation or account of something, presenting the chief factors and omitting minor details and examples
imp	- over exposure of the corporation's data assets which may lead to data theft and increase reputation loss risk.
goal	-
method	-
outcome	-
activity	- to aim (activity) the corporation's data assets (spotlight) by defining their value, criticality, sensitivity and legal implications.
note	-
idea	- this research will solicit information on the data asset types, risk ratings and legal implications from the data owners and legal department so the use of ops will facilitate the timely and standardized collection of this data.
idea	- idea of recently completed Risk Reports for data value coupled with the use of i scripts to define data, its criticality and sensitivity and to determine legal implications.
step	- The primary data will be scanned to completed g showing data types by sensitivity, legal requirements, reputation and other risk
idea	- The data classification grid will be used to determine access permissions appropriate to a particular information asset based on an asset owner's assessment and be the baseline for the Corporation's data asset step . The protocol will be used in corporate governance to gain that of assured information assets.

step	- Resolve something into a whole from its component part.
imp	- there is a concern that provision of IT services is not aligned with strategic organisational goals.
goal	-
method	-
outcome	-
activity	- to step (activity) the various aspects of IT service delivery (spotlight) by examining delivered services to see what practices are involved.
note	-
idea	- in this case I need to gain a thorough idea of service delivery but at this stage I regard it as relatively unknown idea is needed and so it seems best to use step method to look for delivery exemplars or their opposite.
point	- essentially this is about business performance issues and how performance is assured in part at least by IT service. With this backdrop in mind I idea to trace various IT services and their outworking and effects in business units. For this to be successful it will be necessary to obtain a list and description from the IT department beforehand of the various IT services commonly used in the organisation that might be regarded as business critical.
step	- based on interview transcripts I will extract perceived uses and needs and match this to the service definitions provide by the IT department. The collection of data will be expressed in form and prioritised by a consideration of its essentiality to business but each entry will be a service delivery exemplar (positive or negative).
goal	- using the list of exemplars I will idea idea to
goal	to the current practices so that IT service delivery matches needs so that IT managers can use it to get to the
goal	of IT service goals being more strongly aligned with business goals.

Some of you seem to be getting their ideas in a muddle because they are striving to PROOVE something. In Research proving something is extremely difficult at the best of times and some things are impossible to prove. Writers going right back to the earliest times have grappled with the idea of proof and you will find the philosophical literature packed with books and articles on this one idea. We will be simple about it and start with the two, perhaps, main strands of thought: inductive and deductive reasoning.

Cause and Effect

It is as well when you read these notes to remember that everything one way or another has a cause. So if your accounting system malfunctions then there is cause or really a train of causes and effects: first effect is data input routine fails - cause of input routine failure programming error, causes of programming error is a mistake in the specification and so on.

Don't run away with this idea as in life there are many, many things where we can see the effects but have no chance of knowing the cause for certain: someone crashes into your car, you lose your wallet, you get short sighted and so on.

Research therefore is often at its root about seeing an effect and then looking for a cause. Once we know the cause we try to create something that we can use to remove the cause and so get rid of the effect we don't want by creating an effect we do want. For example, suppose the effect we see is misuse of IT resources for personal use (that is the effect we don't want) and let us for simplicity say that it is caused by people not knowing the rules of use so we can remedy this situation by creating a set of rules or a policy for IT usage and then when the rules or policy are used say by departmental managers we get rid of misuse (the effect we don't want) and instead we have productive use (the effect we do want).

It perhaps is worth noting here that we need two things: the outcome (rules/policy) and the actor (departmental manager) and that linking of outcome and actor will always be present.

Induction

This just means the inference of a general law from the observations of particular instances or sets of instances. What this means is that you notice something that happens and see that it happens often. It follows that you can infer or guess a general law from your observations. For example, you notice that people in your company tend to be more productive after IT training so you make a generalisation using induction and say "training in IT leads to personal productivity increase".

It is very important you understand that nothing has been proved here and all you have is an indication. It is not a proof because we cannot know what new IT tasks or technologies might occur in the future. One of the greatest modern philosophers, Popper, put it like this. "You can never accurately predict the future because it is impossible for men to know now what they, or others men, will know in the future". It follows that we are never possessed of the data that can allow us to make certain predictions about what may lie over the horizon based on our current stock of knowledge no matter how certain we feel about it.

Deduction

This just means inferring particular instances from a general law. So if for example we use Ohm's law we can predict with certainty the value of current if we know the resistance and voltage applied to a particular circuit.

In research we might think along either of these lines so for example we often set a hypothesis (a guess at general law) and then try to prove it. Alternatively we can go and collect data and by looking at the data see if we can work out what the law involved might be.

So if I were considering a link between personal productivity and IT training then I might take a deductive line and postulate the hypothesis (law if you like) "training always increases personal productivity" or I could take an inductive stance and just collect data and see if I can see (guess) what the "law" might be.

Comment on Induction and Deduction

There is no right and wrong approach here and it's a matter for you to consider what sort of outlook you are taking. Probably in technology we tend to take a more inductive attitude. Now it all may sound simple in the IT training case I mentioned above because using either stance one would collect more or less the same data but it will not always be that simple – for example supposed you were looking at the effects of IT system migration in a rapidly expanding company and project control methods used to manage it then it is now not obvious at all what the link between these two things might be so a deductive stance would be unsuitable here.

You might like to think of Sherlock Holmes the fictional detective of the Victorian era who was famous for making deductions. In one story called "The Cardboard Box" he visits a client and sees a photograph on the wall and deduces that the client has two sisters. If you like he used a general law: people have sisters and he uses that general law to deduce a particular instance of it: that his client has sisters. Notice here that such a deduction would not always be true but would be always reasonable.

You might further notice that this is not induction. It might look like it in that the photograph looks like data on which we might guess at some general law. This is not so however, since one cannot look at a photograph of three people and infer a law from it about sisters. Logically, we can say that many or most women have sisters therefore a particular woman probably has one. However, we cannot say a particular woman has a sister therefore all women have sisters. To put it more simply, we can say that if all boys are bad and Fred is a boy, therefore Fred is bad. But it is obvious we cannot say Fred is a bad boy therefore all boys are bad. In summary we cannot argue from the particular to the universal but we can argue from the Universal to the particular.

Proof

This means that the phenomenon we are looking at is always true. Now, in practice, proof might be constrained or unconstrained. For example Archimedes principle is unconstrained, meaning it is always true for everyone, all the time, everywhere and is accepted by all. But if we set up an experiment to try to prove that Google email is efficient – it will be constrained in that it is obvious that it is very unlikely to be true for everyone, all the time, everywhere and is accepted as true by everyone. In fact in this case it is severely constrained in that even if you managed to show statistically that it was true then at best one could only say that it applies to the sample used in the study. Additionally, using Poppers idea mentioned above it is obvious we cannot know what will happen in the future.

Notice that I say above that one characteristic of proof is that it is accepted by all but you would be surprised how often that is ignored. Just one ludicrous example will illustrate this, a student told me a story (it may be apocryphal) about an aged Saudi Arabian cleric who in 1977 issued a fatwa (a ruling) that the world was flat! So don't be surprised if people disagree with you even when the evidence seems overwhelming.

Indicators

This is where we talk about indicators - that is in the email study we might be deductive and infer or indicate that Google email is likely to be efficient for most users – that is indicators are not proof but generalisations made on the basis of some evidence (data) we might have. Think of it like this – suppose you invented a wonder pill that you claim would make you see in the dark. Now proving that it works for everyone, all the time and everywhere means that YOU are prepared to guarantee it is true. If it later turns out that for ME it did not work when I was driving my car at night and I ended up crashing and killing 40 goats, 2 chickens, a pedestrian and an onion salesman then I will sue you for £100M!

On the other hand we can be constrained and think in an inductive manner and say that "it has been shown to work in many cases" – that is all we are prepared to give is an indicator (a generalisation) because we have some evidence that it works but not a cast iron guarantee. You might like to link this idea of constrained to setting confidence intervals in statistics.

Sophistry

Much that you will read on the internet in particular can only be classed as sophistry that is clever but worthless argument. The Sophists arose as philosophers more or less at the same time as Socrates in ancient Greece and felt themselves to be very wise men who knew everything in contrast to Socrates who claimed he knew nothing. The Sophists it seems were not much interested in truth but only in winning an argument and many believe they in effect sowed the seeds of the demise of the Greek nation at that time. This may all have happened 2,500 years ago but their legacy lives on and the corrosive influences of their attitude is evident everywhere today and certainly in politics and religion.

As it happens I was discussing these ideas with a student a few days ago in this cohort and she pointed me to a site written by Dr Gary Miller. Dr Miller invites us to use his materials freely so I will do that to illustrate several things about proof. On this site he wrote many things which he regards are some sort of proof and he says it is possible to set standards for truth and talks about falsification tests. Here is one example of the kind of argument he uses.

(http://www.islamicinvitationcentre.com/articles/gary_miller/quran/Quran.htm#Intro)

An engineer at the University of Toronto who was interested in psychology and who had read something on it, conducted researched wrote a thesis on Efficiency of Group Discussions. The

purpose of his research was to find out how much people accomplish when they get together to talk in groups of two, three, ten, etc. The graph of his findings: people accomplish most when they talk in groups of two. Of course, this discovery was entirely beyond his expectations, but it is very old advice given in the Qur'an: "Say, 'I exhort you to one thing - that you stand for Allah, [assessing the truth] by twos and singly, and then reflect....'"

1. So we must look at this and see whether it can in any way be regarded as proof. We might easily observe straight away that there are no references and it is impossible for us to check what has been said as it's a hopeless task to find "An Engineer at the University..." He quotes the Qur'an but does not tell us the surah or the English translation it is taken from (or did he translate it himself or even just make it up). When you see this kind of extremely poor scholarship one has no alternative but to ignore Dr Miller's work entirely as it cannot be trusted. That does not mean Dr Miller is a bad person, all we are saying is that his work cannot be trusted.

2. You may also note that the quotation from the Qur'an is extremely short and that would make me wonder if he is just being very selective to try to make his own point – that is the quote in full might not support his conjecture so he ignores the bits that don't suit him. Again because we have no references we cannot easily check it.

Also notice that he adds something to the Qur'an "that you stand for Allah, [assessing the truth]" and so he perhaps forces an interpretation on the words "that you stand for Allah" but like any interpretation it is only one of many. Additionally, he assumes that it means assessing the truth of anything and it is almost impossible to see that the actual Qur'anic verses are saying that. Overall this looks like Dr Miller is being tendentious (the author simply wants to convince you of something and may use any means to do it) in the extreme.

3. What is he trying to prove here? That the Qur'an agrees with an Engineer's findings? That the Engineer has verified something the Qur'an has said? Is he offering an interpretation of the Engineer's finding or the Qur'an. We simply don't know for sure what point he is making.

4. It is interesting to note here that if this Engineer or the Qur'an is saying that working in two's is powerful he might like to recall that Socrates made the same observation, which he called his dialectical, with impeccable logic about 2,500 years before the Engineer was even born and about 1,000 years before any copies of the Qur'an existed. If you want to follow this up there is an excellent tape by Mark Forstater called "The Living Wisdom of Socrates", Hodder Headline Audio books which is a very engaging introduction to the teaching and life of Socrates.

This point is quite important and that is why we must read widely otherwise we may well think we have discovered something only to find that it is already known and published and we end up making an ass of ourselves because we have not prepared properly. At worst of course this can also look like plagiarism – to take my example a little further we could argue then that Engineer and the Qur'an both plagiarised the idea of Socrates – but of course we take the obvious solution to be that the Engineer and Prophet Mohammed had no knowledge of Socrates. Whilst we might easily allow that Prophet Mohammed had no knowledge of Greek thinkers (there were no great libraries or the internet 1,400 years ago) we are much less inclined to forgive this Engineer or Dr Miller for not knowing something about Socrates, perhaps the greatest thinker of all time.

In short what this example is saying is that you must be sceptical and careful with what people say and you must ask for evidence. Now of course in everyday life we don't question everything we hear or read otherwise life would be an impossibility but we must always be aware that things may not be what they seem and of course in research and what we read we do need to carefully question what it is because we want to be credible and not make a laughingstock of ourselves.

Ways of Dealing with Proof

There are a number of ways of dealing with this idea of proof and I shall just briefly review them.

Hypothesis

With regard to proof, many students like to write out a hypothesis. There are two stages: write the null and alternative hypothesis and then write down the two (usually) variables involved (dependent and independent variables). Unfortunately these two things are often not done satisfactorily. Let me illustrate.

A student wanted to prove something so he wrote a hypothesis that essentially said that there was a link between IT certification training and personal productivity in support roles. He then went on to define the variables as: Role of IT (independent) and Personal Productivity (dependent). Now this will ONLY makes

sense if you can quantify the variables productivity (which is quite easy) and 'Role of IT' which it seems cannot be quantified.

Now in research people tend to treat the idea of hypothesis and the notion of proof in two ways:

Formal - to set up an experiment with two samples one exposed to some effect and one not. So just to be simple I could set up a hypothesis based on say those who have been trained and those not and see if there is any difference in their productivity. This is quite complicated and difficult to do. Even then what would it mean if I could show that there was a link – would it be true/false for all time, everyone and everywhere or would it just be true/false for my sample?

Informal - Instead we could just have what might be called a tentative hypothesis that suggests that there may be a link and then use case studies to demonstrate this. Notice that we are NOT proving anything here only indicating/suggesting something might be true.

Setting Standards/Definitions

It is easily acknowledged that in normal life we can almost never get what one might call absolute proof. In courts of law for example they talk about the evidence being "beyond reasonable doubt" or based on "the balance of probabilities" – in other words you get enough information to convince (but not absolutely prove) you of the truth. This may be done in many ways but usually one lists the things one wants to see. For example, if I wanted to prove that Manchester United is the best football team in the world (they are not because everyone knows that is Arsenal!) then I might lay out my standard or definition for proof: no of goals scored, championships won, number of world class players and so on.

There are three problems with this approach: whoever you are talking to has to agree to your standards or definition, if I can prove it today will it still be true tomorrow and once one knows the standards it is all too easy to find the necessary evidence (one might often say manufacture the evidence).

If you want to think more about this you could look at the way Socrates 2,500 years ago uses this idea in his dialogues - one of the most famous was about beauty. Socrates was by all accounts ugly and he entered into debate with Critobulus who was a very handsome man. Socrates simply asked Critobulus what standard or definition of beauty he was using and Critobulus duly offered a definition which on the surface sounds credible. Socrates, then easily proved using the definition that in fact, contrary to popular opinion Socrates was handsome and Critobulus ugly - an obvious absurdity to any observer of beauty!

A vignette may help you here. I came across a true story of a man who had been married for many years but regularly had nightmares as to whether his wife really loved him. He was so bothered by this that he went to see a Church Minister and was told one way (standard/definition) to find proof (evidence) of love was to consider all the little things you wife does for you: wash you shirts, clear you shoes, cook your meals, look after you when you are ill and so on. You can see the "proofs" would be observable but is it really proof, will that man accept the standard or not, will it still be true in a year's time and if the wife knows the standard will she just manufacture the evidence? The fact is that one can never know the answer here absolutely and there will be many things in life that simply cannot be absolutely proved in any rational manner and all that can be done is to feel convinced.

Falsification

This means that a proof is like a chain with links – break one link and the chain fails. So in proof if you can find one contrary example then the proof fails. In life of course it is all too easy to just ignore contrary opinion or examples and go on only looking for supporting ones. No doubt you have come across many people like this (you or I may be one of them!!), no matter what you say to them they refused to be shifted from their own view even when the evidence is there.

Sometime you see this very strong idea distorted. Where you see this is with authors who try to show that X is untrue and then say that Y is therefore true. I am not talking here about a hypothesis because often there is no link at all between X and Y. As you may know from many of my examples, I am a student of ancient manuscripts and one argument I have seen many time is this one. The ancient Bible manuscripts are corrupted – that is over time the original manuscripts have been lost but copies were made but added to, changed and so on. Now it is easy to show that there has been corruption and no serious scholar would think otherwise. Now what many proponents of other religions and humanists have said is because that is true (the manuscripts have become corrupted) then their sacred book or idea is not. The argument is something like "I can show that Ford is a bad car therefore Volkswagen is a good one" or even more starkly, "you are wrong therefore I am right."

Note. Just in case you are worried there are such a large number of Bible manuscripts that it is in fact easy to reconstruct the original autographs. Incidentally, the same arguments have been used about the great Greek writers and Shakespeare.

Just to whet your appetite I might say that scholars who use the ancient manuscripts have what is called a “critical apparatus” or a process if you like for reconstruction of the original. Later I will be introducing you to various critical apparatus that you will be using to process data in your project. In technology we don’t usually say critical apparatus but instead we say Research Method or more simply problem solving method.

Proof by the Unexpected

Most often when we are working on a topic we have an expectation about the answer so that when we actually see it we feel sort of reassured about it. Now, sometimes we can be surprised and startled by an answer because it is just “too good to be true”. If one takes my hobby as an example, whenever an ancient manuscript is found we expected it to be corrupted or contain errors or emendations – why? Because before the days of the printing press it is just about impossible that a scribe could copy a document of any length by hand without making any errors or not being tempted to “correct” the manuscript or “improve” it in some way.

Sometimes the errors were deliberate because someone wanted the manuscript to take on his particular viewpoint or often it was done for gain. Shakespeare was often illegally “simplified” so that copies could be sold in the street or around theatres for profit.

Therefore if any one comes along and says their manuscript is not corrupted we automatically take a very, very sceptical attitude – it is just not credible and one tends to say it is probably a later forgery or at least there must be something wrong with it.

To give a technical example, some years ago I was researching software testing ideas and I had 5 sets of data based on different criteria. Scatter plots were used and the results from set 4 were just “perfect” and I was almost dancing with joy, a bit like Archimedes I wanted to cry out “Eureka” as I thought I had really uncovered a very important principle. However, the results were just “too good to be true” so that scepticism kicked in and I thought I have to check this. Sadly, what I had done was include just one sample point from test sequence 1 into the data for test sequence 4 and that one mistake had biased the results to such an extent that they were worthless.

Proof by Example

Many authors try argument as a way of proof. One often sees this in religion and politics but it is also present in many technical papers we see. The idea is that I present my view on something and then proceed to “prove” it by instancing examples that endorse its truth and often those who use this idea challenge you to find a contrary example.

I rather like this approach but one just needs to be ultra careful that we are not taken in by our own arguments and get to a stage where we just want to keep convincing ourselves that we are right and fail to see weaknesses in our own thinking. When you use this form your logic must be impeccable and you must get evidence that can be checked but always keep in mind that your arguments are almost bound to be constrained. Dr Miller’s page above is a useful one to look at as he rarely uses any sort of consistent logic or evidence and frankly seems to have lost all sense of scope and now sees everything and every example as supporting his own ideas.

Does it Work

It is always very strong when you can show that something works. That is you have a theory and although you perhaps cannot prove it in any absolute sense you can show that it works by citing examples. For example, some project management techniques are like this as we can see them working but if one is sensible one just recommends them as likely to work as no one would be willing to offer a guarantee that they always work no matter what the circumstances or project.

Monk, R and Raphael, F (ed), (2000), *The Great Philosophers* published, Phoenix ISBN 0-75381-136-7

Project Proposal –

1. Title –Document Management strategies (78)

2. Background-

Document management strategy is intrinsically linked to the development, evolution and optimization of its operating processes in many organizations. Document Management for the Enterprise simplifies the principles of document engineering and management. Document management is one tool among several collaborative computing tools necessary for users to manage information.

3. Presenting market potential –

The company's massive scope of operations and their geographical spread meant that large volumes of data of varied genre were being created at dispersed locations. So now it is essential for organizations to organized contents/ documents in a way that optimized its usefulness to multiple users across the organization. Document management solution should reduce cost of ownership for both purchase and administration by integrating document management into an existing collaborative/information management solution.

4. Real-world target-

Convince organization to implement document management strategies which will enable them to access information dispersed throughout the organization, whether local or global and effectively provides quick, easy access to information regardless of the source.

5. Research question –

To develop and agree whole-life document management strategy and implement a solution that will cover both internal and external procedures with standards for processes and document.

6. Personal theory –

To overcome information overload by giving users the ability to organize, filter, prioritize and manage a variety of data types we need to convince enterprises to implement document Management strategies in business processes.

7. Intended project outcome –

My expected outcome will be set of benefits and explanation of in- depth features and functionality of data management strategies in maintaining huge data bases in enterprises.

8. Strategic IT value –

By Uniting the various repositories for files and documents organization can keep track of their data bases by date, process, type, status and priority wise to efficiently maintain their business processes. Document management solution handles documents by electronically storing, organizing, indexing and filing. They can be retrieved when required, without any loss of time. The cost of miss management of documents is too high.

9. Design for collecting data –

Scope of this study to know the life cycle management of documents to draw what kind of

benefits firms can make by implementing a document management system in current business processes.

10. Design for processing primary data -

Study the behavior and attitudes of different industries with the help of cases and tools which they have implemented and leveraging the strengths in best possible means to improve their customer centricity in low cost by using document management strategies.

Project Proposal –

1. Title – Impact of IT on international supply chain management (36)

2. Background-

Supply chain management (SCM) is the practice of coordinating the design, procurement, and flow of goods, services, information and finances, from raw material to parts supplier, to manufacturer to distributor, to retailer to consumer. This process includes product design, order generation, order taking, information feedback and the efficient and timely delivery of goods and services.

3. Presenting market potential –

Information technology and the Internet have revolutionized the way companies do business. They have changed the way organizations operate by enabling the re-engineering of sourcing, production and logistics processes

4. Real-world target-

The classic objective of logistics is to be able to have the right products in the right quantities (at the right place) at the right moment at minimal cost. Increased competition, ever expanding product variety, and more demanding consumers require more efficient supply chains

5. Research question –

How to effectively manage the supply chain using information technology is a topic of discussion in all levels of management, regardless of industries?

6. Personal theory –

I think IT in SCM presents both challenges and opportunities for supply chain managers because of its ability to collapse time and distance. Keeping this in mind firm needs to be understand the implication of supply chain management implementation in their transaction processes.

7. Intended project outcome –

My expected outcome will be a set of examples probing the utilization of IT in supporting supply chain management by developing a set of metrics to monitor the supply chain so that it is efficient, costs less and delivers high quality and value to customers.

8. Strategic IT value –

This research study provides a realistic portrayal of a key benefit of information technologies in supporting buyer-seller relationships. Using IT in SCM companies can follow a practice known as just-in-time manufacturing, and it allows companies to reduce the amount of inventory that they keep. This can cut costs substantially, since they no longer required to produce and store excess goods.

9. Design for collecting data –

I will collect the sample data from companies willing to share openly their results which have achieved using Information technology in their supply chain management.

10. Design for processing primary data –

On data collection an analysis will be done which will include the process description and the technology used. The in-depth benefits will be identified on the basis of qualitative and quantitative data available.

Project Proposal –

1. Title – High speed Broadband and its business impact (197)

2. Background-

High-speed Internet access or “broadband” allows users to access the Internet and Internet-related services at significantly higher speeds than those available through “dial-up” Internet access services. Broadband allows users to access information via the Internet using one of several high-speed transmission technologies.

3. Presenting market potential –

Broadband extends the LAN over the geographical boundaries and enables maximum interactivity. There are a large number of processes that can be put on line and enabled by the Network to make it easier and handy. For example Workforce optimization, many human resources administrative functions can be processed on-line, vacation approval, performance reviews, and definition of fiscal year MBO's and action plans, among others. Many software updates and technical ICT issues can be also addressed on-line.

4. Real-world target-

Having broadband connections in remote and rural area can be used as a e-business tool to buy and sell various goods and services over the internet thus saving lot of time and cost. Other areas of usefulness can be healthcare, education and government services to name a few.

5. Research question –

How broadband availability can have an important impact upon the productivity and growth of both business organizations and national economies?

6. Personal theory –

Broadband is predicted to have a considerable impact on small and medium-sized enterprises (SMEs) bringing the advantages of high-speed, high-capacity communications within their reach. Also the rural community can use broadband as an e-business tool to buy n sell various services and thus contributing to boast up the economy.

7. Intended project outcome –

The output will be a set of in-depth business case studies providing background information on each business and detailing the business case and subsequent benefits of a broadband Internet connection.

8. Strategic IT value –

Adaptation of broadband, e-commerce and public websites have allowed small and medium-sized enterprises to deliver new productivity, efficiency and an enhanced customer experience to their business while leveraging their limited human resources.

9. Design for collecting data –

My process will follow case study by involving industries experience in using high speed broadband connection at work.

10. Design for processing primary data -

Once the secondary data is collected I will outline the benefits/advantage and barriers of using broadband service in different industries.

Project Proposal –

1. Title –Document Management strategies (78)

2. Background-
